Module 08
Multiattribute Utility Theory:
Example Application in Design and Manufacturing

Dr. Jitesh H. Panchal

Decision Making in Engineering Design

School of Mechanical Engineering
Purdue University, West Lafayette, IN
Module Outline

1. 3D Printing Application

2. Example: Light Switch Cover Plate
   - 1. Assessing the Multi-attribute Utility Function
   - 2. Choosing Alternative based on the Utility Function

3D Printing Application

Example: Light Switch Cover Plate
3D Printing Processes

- FDM: Fused Deposition Modeling
- Polyjet
- SLA: Stereolithography
- SLS: Selective Laser Sintering
- DMLS: Direct Metal Laser Sintering
Fused Deposition Modeling (FDM)

Fused Deposition Modeling is an additive manufacturing process which is used to build concept models, functional prototypes and end-use parts with engineering-grade and high accuracy thermoplastics. The FDM technology is designed to create with production-grade thermoplastic materials that possess the most mechanical, thermal and chemical strength.

Stereolitography (SLA)

Stereolitography is one of the most advanced and accurate rapid prototyping technologies, which is most ideal for concept modeling, fit-form-function testing and a variety of molding techniques. In an SLA process, the laser is capable of fusing metal, plastic, glass and ceramic particles into a 3D Printed model. Offering a variety of different coloured materials, SLA is an ideal technology for economical and rapid 3D printing.

Diverse Applications of 3D Printing

- Concept Modeling
- Display Parts Finishing
- Fastening and Gluing
- Fit and Form Testing
- Functional Testing
- Heat Resistance Testing
- Manufacturing-Tooling
- Medical and Dental Tooling
- Rubber Part Testing
- Shape Changing
- Surface Improvement
Example: Light Switch Cover Plate
Objectives of the Prototype:
- functional product validation, particularly with respect to the snap-fitting of components,
- determining closeness of fit or tolerance of the two interfacing components,
- obtaining a feel for the product, and
- visual and physical confirmation of 3D interface integrity
Identifying Attributes

1. Tensile strength: The strength of the material under tension
2. Young’s modulus: The modulus of elasticity of the material
3. Flexural strength: The strength of the material under bending
4. Flexural modulus: The modulus of flexural stiffness of the material
5. Detail capability: The ability to reproduce the part in sufficient detail.
6. Accuracy: The ability to reproduce the part with sufficient accuracy (maintaining dimensional requirements)
7. Elongation at break
8. Hardness
9. Density
10. Heat Deflection
11. Durability
12. Build Time
13. Cost
Assessment Procedure for Multiattribute Utility Functions

1. Introducing the terminology and ideas.
2. Identifying relevant independence assumptions.
3. Assessing conditional utility functions or isopreference curves.
4. Assessing the scaling constants.
5. Checking for consistency and reiterating.

Refer to Modules 6 and 7.
Goal: To simplify utility assessment.

Determine whether one (or more) of these conditions is (are) satisfied.

1. Preferential Independence
2. Conditional Utility Independence
3. Mutual Utility Independence
4. Additive Independence

Rest of the slides are based on the assumption that Additive Independence condition is satisfied, i.e.,

\[ U(x_1, x_2, \ldots, x_N) = \sum_{i=1}^{N} k_i u_i(x_i) \]

Refer to Module 7.
Step 3: Assessing Conditional Utility Functions, $u_i(x_i)$

**Procedure:**

1. Preparing for assessment
2. Identifying the relevant qualitative characteristics
3. Specifying quantitative restrictions
4. Choosing a utility function
5. Checking for consistency
Attribute: Tensile Strength

Monotonicity: Non-monotonic. Utility is maximum at the target value.

- Lower Unacceptable: 50 MPa
- Ideal: 65 MPa
- Upper Unacceptable: 75 MPa

Risk attitude: Risk averse
Step 3: Assessing Conditional Utility Functions
Quantitative Characteristics

The chosen functional form: \( u(x) = a + bx + ce^{dx} \)

For this function, the risk measure,

\[
    r(x) = -\frac{u''(x)}{u'(x)} = -\frac{d^2e^{dx}}{(\frac{b}{c} + de^{dx})}
\]

Question
Under which conditions does this function model risk aversion?
Step 3: Assessing Conditional Utility Functions

Quantitative Characteristics

**Tensile Strength:**
- Lower Unacceptable: 50 MPa
- Ideal: 65 MPa
- Upper Unacceptable: 75 MPa

Split the utility function into two parts and set scale:
- Left Side Utility Function:
  \[ u_L(50) = 0, \quad u_L(65) = 1 \]
- Right Side Utility Function:
  \[ u_R(65) = 1, \quad u_R(75) = 0 \]
Step 3: Assessing Conditional Utility Functions

Quantitative Characteristics

Lottery question 1:

\[ (50, 0.5, 65) \sim x_{0.5} \]

Say answer is: \( x_{0.5} = 54.43 \)

Lottery question 2:

\[ (50, 0.5, 54.43) \sim x_{0.25} \]

Say answer is: \( x_{0.25} = 51.75 \)
Step 3: Assessing Conditional Utility Functions

Quantitative Characteristics

Lottery question 3:

\( \langle 54.43, 0.5, 65 \rangle \sim x_{0.75} \)

Say answer is: \( x_{0.75} = 58.88 \)

Curve Fit: \( u(x) = a + bx + ce^{dx} \)

\( u_L(x) = 1.022 - 2981e^{-0.16x} \)
Step 3: Assessing Conditional Utility Functions

Quantitative Characteristics

\[ u_L(x) = 1.022 - 2981e^{-0.16x} \]
\[ u_R(x) = 2.018 - 0.01103e^{0.06934x} \]
Step 4: Assessing the Scaling Constants

Additive Multi-attribute Utility Function,

\[ U(x_1, x_2, \ldots, x_N) = \sum_{i=1}^{N} k_i u_i(x_i) \]

**Approach:** To find \( k_i \), use indifference questions such as:

\[
\begin{align*}
(TS_0, YM_{0.55}, FS_{0.55}, FM_{0.55}, DC_{0.55}, A_{0.55}) & \sim \\
(TS_?, YM_{0.45}, FS_{0.45}, FM_{0.45}, DC_{0.45}, A_{0.45})
\end{align*}
\]

Need \((N - 1)\) such questions to estimate \( k_i \).

---

Note: This is not a lottery question.
Step 4: Assessing the Scaling Constants

Outcome

2. SLA3500 with SL7510 (by Vantico AG)
3. SLA3500 with DSM8120 (by DSM Somos®)
4. FDM1650 with P400 (by Stratasys Inc.)
5. MJM2100 with TJ75 (by 3D Systems)
3D Printing Application
Example: Light Switch Cover Plate

1. Assessing the Multi-attribute Utility Function
2. Choosing Alternative based on the Utility Function

Probability Distributions of Attributes for an Alternative
Example: SLA250-DSM7110

Determine these for each attribute for each alternative!
Evaluate the Expected Utility for Each Alternative

For the additive multi-attribute utility function,

$$U(x_1, x_2, \ldots, x_N) = \sum_{i=1}^{N} k_i u_i(x_i)$$

The expected utility,

$$E[U(x_1, x_2, \ldots, x_N)] = \sum_{i=1}^{N} k_i E[u_i(x_i)]$$

Therefore, first calculate the expectation of the single-attribute utility functions, and then scale them.
Evaluate the Expected Utility for Each Alternative

Tensile Strength for SLA250-DSM7110

\[ E[u(x)] = \int p(x)u(x)dx \]

Denote this as: \( E[u_1(TS)] \)
Evaluate the Expected Utility for Each Alternative

Expected Utility for an Alternative:

\[ E[U(x_1, x_2, \ldots, x_N)] = \sum_{i=1}^{N} k_i E[u_i(x_i)] \]

\[ = k_1 E[u_1(TS)] + k_2 E[u_2(YM)] + k_3 E[u_3(FS)] + k_4 E[u_4(FM)] + k_5 E[u_5(DC)] + k_6 E[u_6(A)] \]
### Results: Expected Utility
