7 in	Schmitt Trigger Operation
0	V <sub>out</sub> is high
$V_{ m DD}$	Once $V_{\text{in}}$ touches $V_{\text{trip,n}}$ , nFET turns on and $V_{\text{out}}$ goes to low.
, DD	$V_{\rm out}$ is low
$\rightarrow 0$	Changed $V_{\text{trip,p}}$ due to the forward sweep of $V_{\text{in}}$ results Schmitt Trigger operation.

 $_{\text{piasp}} = 0.6$ 

V<sub>biasn</sub> [V]

✤ Oscillation triggering is controlled by transmission gate Scillation frequency can be designed by the equation below:  $f = \left(2\alpha \cdot \left\{R_{on} \cdot C_{out,eff} + C_{in,eff} \cdot \left(R_{on} + R_{TG}\right)\right\} + t_{p,LH} + t_{p,HL}\right)^{-1}$ the factor  $\alpha$  relates (dis)charging delay of  $C_{in}$  to the voltage swing at the input node • Energy consumption per a single cycle: 0.84 nJ ( $V_{DD}$  = 0.9 V) ~  $3.97 \text{ nJ} (V_{\text{DD}} = 1.2 \text{ V})$ . This is at least 29x lower compared to the  $V_{\rm DD} = 1.1 \, {\rm V}$ previous work.
