Markov Chains

- Markov process: Probability distribution for future state only depends on the present state, not on how the process arrived at the present state
- Markov chain: State space is discrete
- Discrete time Markov chain: Time is discrete
- $X_0, X_1, ..., X_n, ...$: observed state at discrete times $t_0, t_1, ..., t_n, ...$
- $X_n = j \implies$ system state at time step n is j.
- P($X_n = i_n | X_0 = i_0, X_1 = i_1, ..., X_{n-1} = i_{n-1}$) = P($X_n = i_n | X_{n-1} = i_{n-1}$) (Markov Property)
- $p_{jk}(m,n) \equiv P(X_n = k \mid X_m = j), \ 0 \le m \le n \text{ (conditional pmf)}$
- $p_j(n) \equiv P(X_n = j) \quad \text{(unconditional pmf)}$

ECE 60872 2 PURDUE

Homogeneous Markov Chain

- □ Homogeneous Markov chain: $p_{ik}(m,n)$ only depends on n-m
- □ n-step transition probability: $p_{ik}(n) = P(X_{m+n} = k \mid X_m = j)$
 - 1-step transition probability: $p_{jk} = p_{jk}(1) = P(X_n = k|X_{n-1} = j)$
- Initial probability row vector: $\mathbf{p}(0) = [p_0(0), p_1(0), ..., p_k(0), ...]$
- Transition probability matrix:

$$P = [p_{ij}] = \begin{bmatrix} p_{00} & p_{01} & p_{02} & \cdot & \cdot \\ p_{10} & p_{11} & p_{12} & \cdot & \cdot \\ \vdots & \vdots & \vdots & \cdot & \cdot \end{bmatrix}$$

ECE 60872 3 PURDUE

Markov Chain Example

1. System is in state 0 if it is operational, state 1 if it is undergoing repair. Homogeneous DTMC process.

$$P = \begin{bmatrix} 1-a & a \\ b & 1-b \end{bmatrix}, 0 \le a, b \le 1$$
2. A sequence of successive software runs, each run has two

2. A sequence of successive software runs, each run has two possible outcomes: success or failure. X_n denotes outcome of nth run (0 for success, 1 for failure). Occurrence of failure in a run depends on the outcome of previous run.

ECE 60872 4 PURDUE

Computation of n-step Transition Probabilities

State i to j in n steps

- $p_{ij}(n) = P(X_{m+n} = j \mid X_m = i)$
- Events: State reaches k (from i) & reaches j (from k) are independent due to the Markov property (i.e. no history)
- Invoking the theorem of total probability:

$$p_{ij}(m+n) = \sum_{i} p_{ik}(m) p_{kj}(n)$$

Let P(n): n-step prob. transition matrix (i,j)th entry is $p_{ij}(n)$. Making m=1, n=n-1 in the above equation:

$$P(n) = P.P(n-1) = P^n$$

$$p_j(n) = P(X_n = j) = \sum_i P(X_0 = i)P(X_n = j|X_0 = i) = \sum_i p_i(0)p_{ij}(n)$$

ECE 60872 5 PURDUE

Computation of n-step Transition Probabilities

 \Box The pmf of the random variable X_n is

$$p_j(n) = P(X_n = j) = \sum_i P(X_0 = i)P(X_n = j|X_0 = i) = \sum_i p_i(0)p_{ij}(n)$$

j, in general can assume countable values, 0,1,2,
 Defining,

$$\mathbf{p}(n) = [p_0(n), p_1(n), \dots, p_j(n), \dots]$$

 $p_j(n)$ for j=0,1,2,...,k,... can be written in the vector form as, $[p_0,p_1,p_2,...,p_i,...](n) =$

ECE 60872 6 PURDUE

Two state Markov chain example

For a two state DTMC, say the transition prob. matrix is

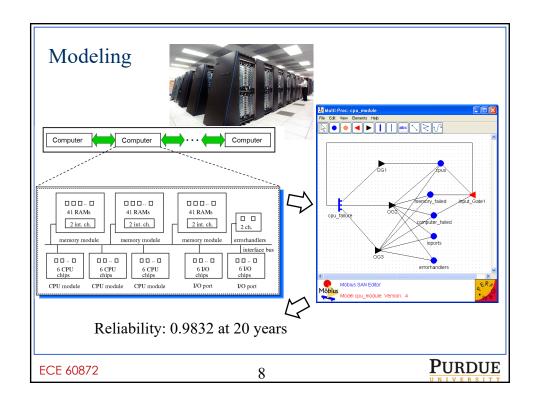

$$P = \left[\begin{array}{ccc} 1-a & a \\ b & 1-b \end{array}\right]$$
 , $0 \leq a,b \leq 1$, $|1-a-b| < 1$

Then, the n-step transition probability matrix $P(n) = P^n$ is

$$P(n) = \begin{bmatrix} \frac{b+a(1-a-b)^n}{a+b} & \frac{a-a(1-a-b)^n}{a+b} \\ \frac{b-b(1-a-b)^n}{a+b} & \frac{a+b(1-a-b)^n}{a+b} \end{bmatrix}$$

- Example: Consider a communication network consisting of a sequence of binary communication channels, with a=1/4, b=1/2. Here X_n denotes the bit leaving the nth stage and X_o represents the bit entering the system.
- 1. If a bit enters as 1, what is the probability of being correctly transmitted over (a) two stages (b) three stages?
- 2. Assuming initial probabilities $P(X_0=0) = 1/3$ and $P(X_0=1) = 2/3$, what is $\mathbf{p}(\mathbf{n})$?

ECE 60872 7 PURDUE

Stochastic Activity Networks

Stochastic activity networks, or SANs, are a convenient, graphical, high-level language for describing system behavior. SANs are useful in capturing the stochastic (or random) behavior of a system.

Examples:

- The amount of time a program takes to execute can be computed precisely
 if all factors are known, but this is nearly impossible and sometimes useless.
 At a more abstract level, we can approximate the running time by a random
 variable.
- Fault arrivals almost always must be modeled by a random process.

9

We begin by describing a subset of SANs: stochastic Petri nets.

PURDUE

ECE 60872

Stochastic Petri Net Overview One of the simplest high-level modeling formalisms is called *stochastic* Petri nets. A stochastic Petri net is composed of the following components: · Places: which contain tokens, and are like variables NumCPU · tokens: which are the "value" or "state" of a place NumCPU=3 Timed Untimed · transitions: change the number of tokens in places every 30 seconds input arcs: which connect places to transitions CPU consumed every 30 seconds which connect transitions to places · output arcs: CPU is placed in busy place **PURDUE** ECE 60872 10

Firing Rules for SPNs

A stochastic Petri net (SPN) executes according to the following rules:

• A transition is said to be *enabled* if for each place connected by input arcs, the number of tokens in the place is ≥ the number of input arcs connecting the place and the transition.

Example:

Transition t1 is enabled.

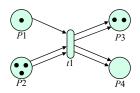

Transition t2 is not enabled.

ECE 60872 11

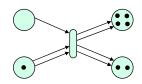

Firing Rules, cont.

- □ A transition may *fire* if it is enabled. (More about this later.)
- If a transition fires, for each input arc, a token is removed from the corresponding place, and for each output arc, a token is added to the corresponding place.

Example:

ECE 60872

12

PURDUE

Specification of Stochastic Behavior of an SPN

- A stochastic Petri net is made from a Petri net by
 - Assigning an exponentially distributed time to all transitions.
 - Time represents the "delay" between enabling and firing of a transition.
 - Transitions "execute" in parallel with independent delay distributions.
- Since the minimum of multiple independent exponentials is itself exponential, time between transition firings is exponential.
- If a transition t becomes enabled, and before t fires, some other transition fires and changes the state of the SPN such that t is no longer enabled, then t aborts, that is, t will not fire.
- Since the exponential distribution is memoryless, one can say that transitions that remain enabled continue or restart, as is convenient, without changing the behavior of the network.

ECE 60872 13 PURDUE

SPN Example: Readers/Writers Problem

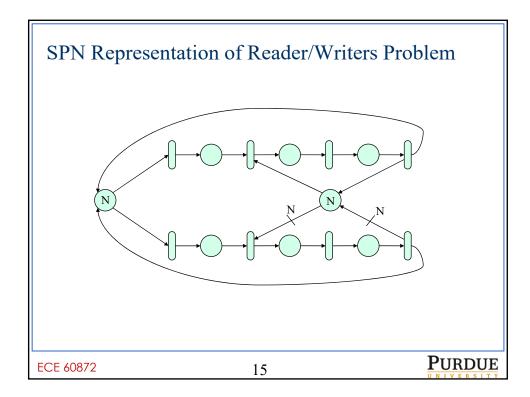

There are at most N requests in the system at a time. Read requests arrive at rate λ_{ra} , and write requests at rate λ_{wa} . Any number of readers may read from a file at a time, but only one writer may write at a time. A reader and writer may not access the file at the same time.

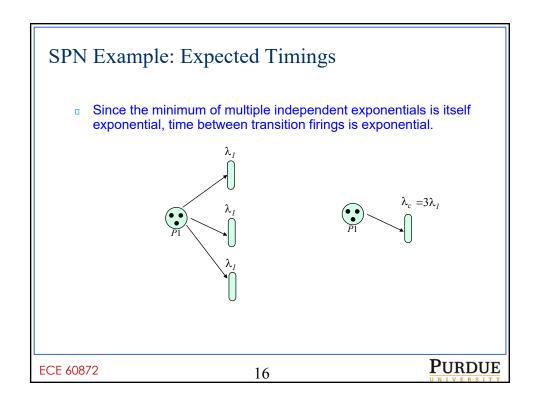

Locks are obtained with rate λ_L (for both read and write locks); reads and writes are performed at rates λ_r and λ_w respectively. Locks are released at rate λ_{rel} .

ECE 60872 14 PURDUE

Stochastic Activity Networks

The need for more expressive modeling languages has led to several extensions to stochastic Petri nets. One extension that we will examine is called *stochastic activity networks*. Because there are a number of subtle distinctions relative to SPNs, stochastic activity networks use different words to describe ideas similar to those of SPNs.

Stochastic activity networks have the following properties:

- A general way to specify that an activity (transition) is enabled
- A general way to specify a completion (firing) rule
- A way to represent zero-timed events
- A way to represent probabilistic choices upon activity completion
- State-dependent parameter values
- General delay distributions on activities

ECE 60872 17 PURDUE

SAN Symbols

Stochastic activity networks (hereafter SANs) have four new symbols in addition to those of SPNs:

- Input gate: used to define complex enabling predicates and completion functions
- Output gate: used to define complex completion functions
- Cases: (small circles on activities) used to specify probabilistic choices
- Instantaneous activities: used to specify zero-timed events

ECE 60872 18 PURDUE

SAN Enabling Rules

An input gate has two components:

- □ enabling_function (state) → boolean; also called the enabling predicate
- $_{\square}$ input_function(state) \rightarrow state; rule for changing the state of the model

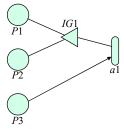

An activity is *enabled* if for every connected input gate, the enabling predicate is true, and for each input arc, the number of tokens in the connected place ≥ number of arcs.

We use the notation MARK(P) to denote the number of tokens in place P.

ECE 60872 19 PURDUE

Example SAN Enabling Rule

Example:

IG1 Predicate:

```
if((MARK(P1)>0 && MARK(P2)==0)||
          (MARK(P1)==0 && MARK(P2)>0))
          return 1;
else return 0;
```

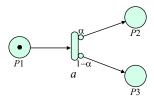

Activity a1 is enabled if IG1 predicate is true (1) and MARK(P3) > 0. (Note that "1" is used to denote true.)

ECE 60872

20

Cases

Cases represent a probabilistic choice of an action to take when an activity completes.

When activity *a* completes, a token is removed from place P1, and with probability α , a token is put into place P2, and with probability $1 - \alpha$, a token is put into place P3.

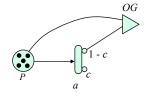

Note: cases are numbered, starting with 1, from top to bottom.

ECE 60872 21

Output Gates

When an activity completes, an output gate allows for a more general change in the state of the system. This output gate function is usually expressed using pseudo-C code.

Example

OG Function

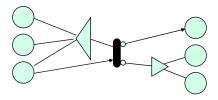

MARK(P) = 0;

PURDUE

ECE 60872 22 PURDUE

Instantaneous Activities

Another important feature of SANs is the instantaneous activity. An *instantaneous activity* is like a normal activity except that it completes in zero time after it becomes enabled. Instantaneous activities can be used with input gates, output gates, and cases.

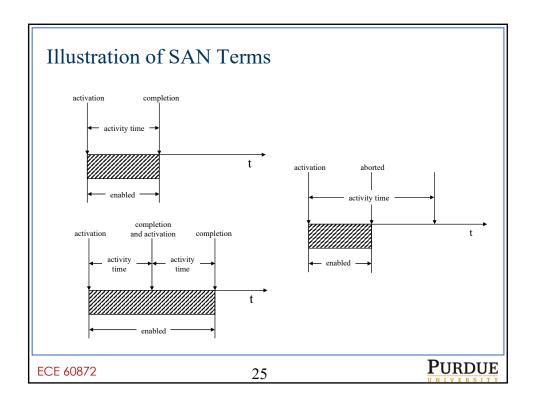

Instantaneous activities are useful when modeling events that have an effect on the state of the system, but happen in negligible time, with respect to other activities in the system, and the performance/dependability measures of interest.

ECE 60872 23 PURDUE

SAN Terms

- 1. activation time at which an activity begins
- 2. completion time at which activity completes
- 3. *abort* time, after activation but before completion, when activity is no longer enabled
- 4. *active* the time after an activity has been activated but before it completes or aborts.

Completion Rules

When an activity *completes*, the following events take place (in the order listed), possibly changing the marking of the network:

- 1. If the activity has cases, a case is (probabilistically) chosen.
- 2. The functions of all the connected input gates are executed (in an unspecified order).
- 3. Tokens are removed from places connected by input arcs.
- 4. The functions of all the output gates connected to the chosen case are executed (in an unspecified order).
- 5. Tokens are added to places connected by output arcs connected to the chosen case.

Ordering is important, since effect of actions can be marking-dependent.

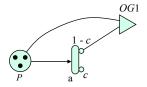

ECE 60872 26 PURDUE

Marking Dependent Behavior

Virtually every parameter may be any function of the state of the model. Examples of these are

- · rates of exponential activities
- · parameters of other activity distributions
- · case probabilities

An example of this usefulness is a model of three redundant computers where the coverage (probability that a single computer crashing crashes the whole system) increases after a failure.

	a
case 1	0.1 + 0.02 * MARK(P)
case 2	0.9 – 0.02 * MARK(P)

ECE 60872 27

Fault-Tolerant Computer Failure Model Example

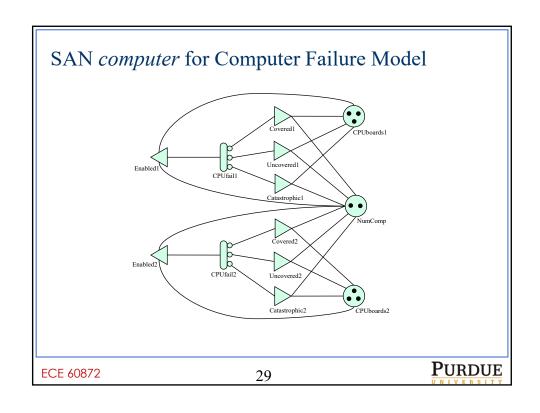

A fault-tolerant computer system is made up of two redundant computers. Each computer is composed of three redundant CPU boards. A computer is operational if at least 1 CPU board is operational, and the system is operational if at least 1 computer is operational.

CPU boards fail at a rate of 1/10⁶ hours, and there is a 0.5% chance that a board failure will cause a computer failure, and a 0.8% chance that a board will fail in a way that causes a catastrophic system failure.

Reward Variables

- Reward variables are a way of measuring performance- or dependability-related characteristics about a model.
- Examples:
 - Expected time until service
 - System availability
 - Number of misrouted packets in an interval of time
 - Processor utilization
 - Length of downtime
 - Operational cost
 - Module or system reliability
- Types:
 - A model may be in a certain state or states for some period of time, for example, "CPU idle" states. This is called a *rate reward*.
 - An activity may complete. This is called an *impulse reward*.

ECE 60872 32 PURDUE

```
Reward Variables for Example
        Reliability
                Rate rewards
                    Subnet = computer
                         Predicate:
                             \overline{MAR}K(NumComp) > 0
                         Function:

Mobius Software

- Graphically builds and simulates SAN's
- Includes abstraction:
 - Models
 - These can be either atomic models or other composed models
 - · Cycles are not allowed
 - Join nodes
 - Join nodes define a set of shared variables that are joined across the child models and nodes
 - · Shared variables must all have the same type and initial value
 - Rep nodes
 - Rep nodes define a set of identical replicas and a set of shared variables across those replicas

ECE 60872 35 PURDUE

Mobius Examples (v 2.5)

- Running an Existing Example:
 - Projects -> Unarchive (Multi-Proc)
 - Projects -> Open (Multi-Proc), re-save if necessary
 - Documentation: https://www.mobius.illinois.edu/wiki/index.php/Fault-Tolerant_Multiprocessor_Model
- Note the rewards for tracking performance
- Note the study variable sweeps for the experiments
- Open either the simulation or transformer
- Collect the output (ASCII) and map it to a plot (Excel)

ECE 60872 36 PURDUE

Duplicating Example in Presentation

- Projects -> New
- Double click Atomic
 - SAN Model, give it a name "combined pc model"
 - Replicate the system diagram
 - (Use Variable->Mark() instead of MARK(Variable))
 - Setup the reward
 - Create an experiment/study
 - Use a simulated solver

- Transition probability matrix:

$$P = [p_{ij}] = \begin{bmatrix} p_{00} & p_{01} & p_{02} & \cdot & \cdot \\ p_{10} & p_{11} & p_{12} & \cdot & \cdot \\ \vdots & \vdots & \vdots & \cdot & \cdot \end{bmatrix}$$

ECE 60872 39 PURDUE

Markov Chain Example

1. System is in state 0 if it is operational, state 1 if it is undergoing repair. Homogeneous DTMC process.

$$P = \begin{bmatrix} 1 - a & a \\ b & 1 - b \end{bmatrix}, 0 \le a, b \le 1$$

2. A sequence of successive software runs, each run has two possible outcomes: success or failure. X_n denotes outcome of nth run (0 for success, 1 for failure). Occurrence of failure in a run depends on the outcome of previous run.

$$P(X_{n+1}=1 \mid X_n=0) = 1-p$$

 $P(X_{n+1}=1 \mid X_n=1) = q$

ECE 60872 40

Computation of n-step Transition Probabilities

- □ For a DTMC, find $p_{ij}(n) = P(X_{m+n} = j \mid X_m = i)$
- Events: State reaches k (from i) & reaches j (from k) are independent due to the Markov property (i.e. no history)
- Invoking the theorem of total probability:

$$p_{ij}(m+n) = \sum_{i} p_{ik}(m) p_{kj}(n)$$

Let P(n): n-step prob. transition matrix (i,j)th entry is $p_{ij}(n)$. Making m=1, n=n-1 in the above equation:

$$P(n) = P.P(n-1) = P^n$$

$$p_j(n) = P(X_n = j) = \sum_i P(X_0 = i)P(X_n = j|X_0 = i) = \sum_i p_i(0)p_{ij}(n)$$

ECE 60872 41 PURDUE

Computation of n-step Transition Probabilities

 \Box The pmf of the random variable X_n is

$$p_j(n) = P(X_n = j) = \sum_i P(X_0 = i) P(X_n = j | X_0 = i) = \sum_i p_i(0) p_{ij}(n)$$

j, in general can assume countable values, 0,1,2,Defining,

$$p(n) = [p_0(n), p_1(n), \dots, p_j(n), \dots]$$

 $p_j(n)$ for j=0,1,2,...,k,... can be written in the vector form as, $[p_0 p_1 p_2 ... p_j ...](n) =$

$$\underbrace{\left[\begin{array}{ccccc} p_0 & p_1 & p_2 & \dots & p_j & \dots \end{array}\right](0)}_{\mathbf{p}(0)} \begin{bmatrix} p_{00}(n) & p_{01}(n) & \dots & p_{0j}(n) & \dots \\ p_{10}(n) & p_{11}(n) & \dots & p_{1j}(n) & \dots \\ p_{20}(n) & p_{21}(n) & \dots & p_{2j}(n) & \dots \\ p_{20}(n) & p_{i1}(n) & \dots & p_{ij}(n) & \dots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ p_{i0}(n) & p_{i1}(n) & \dots & p_{ij}(n) & \dots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \end{bmatrix}$$

ECE 60872 42 PURDUE

Two state Markov chain example

For a two state DTMC, say the transition prob. matrix is

P =
$$\begin{pmatrix} 1 - \alpha & \alpha \\ \beta & 1 - \beta \end{pmatrix}$$

The eigenvalues are 1 and $1 - \alpha - \beta$. So we can write

$$P = U \begin{pmatrix} 1 & 0 \\ 0 & 1 - \alpha - \beta \end{pmatrix} U^{-1} \quad \Longrightarrow \ P^n = U \begin{pmatrix} 1 & 0 \\ 0 & (1 - \alpha - \beta)^n \end{pmatrix} U^{-1}$$

So $p_{11}^{(n)} = A + B(1 - \alpha - \beta)^n$ for some A and B.

But
$$p_{11}^{(0)}=1=A+B$$
 and $p_{11}^{(1)}=1-\alpha=A+B(1-\alpha-\beta)$. So $(A,B)=(\beta,\alpha)/(\alpha+\beta)$,

i.e.

$$P_1(X_n = 1) = p_{11}^{(n)} = \frac{\beta}{\alpha + \beta} + \frac{\alpha}{\alpha + \beta} (1 - \alpha - \beta)^n.$$

Note that this tends exponentially fast to a limit of $\beta/(\alpha+\beta)$.

Other components of P^n can be computed similarly, and we have

$$P^n = \begin{pmatrix} \frac{\beta}{\alpha+\beta} + \frac{\alpha}{\alpha+\beta}(1-\alpha-\beta)^n & \frac{\alpha}{\alpha+\beta} - \frac{\alpha}{\alpha+\beta}(1-\alpha-\beta)^n \\ \frac{\beta}{\alpha+\beta} - \frac{\beta}{\alpha+\beta}(1-\alpha-\beta)^n & \frac{\alpha}{\alpha+\beta} + \frac{\beta}{\alpha+\beta}(1-\alpha-\beta)^n \end{pmatrix}$$

Two state Markov chain example

Then, the n-step transition probability matrix $P(n) = P^n$ is

$$P^{n} = \begin{pmatrix} \frac{\beta}{\alpha+\beta} + \frac{\alpha}{\alpha+\beta} (1-\alpha-\beta)^{n} & \frac{\alpha}{\alpha+\beta} - \frac{\alpha}{\alpha+\beta} (1-\alpha-\beta)^{n} \\ \frac{\beta}{\alpha+\beta} - \frac{\beta}{\alpha+\beta} (1-\alpha-\beta)^{n} & \frac{\alpha}{\alpha+\beta} + \frac{\beta}{\alpha+\beta} (1-\alpha-\beta)^{n} \end{pmatrix}$$

- Example: Consider a communication network consisting of a sequence of binary communication channels, with a=1/4, b=1/2. Here X_n denotes the bit leaving the nth stage and X_o represents the bit entering the system.
- 1. If a bit enters as 1, what is the probability of being correctly transmitted over (a) two stages (b) three stages?
- 2. Assuming initial probabilities $P(X_0=0) = 1/3$ and $P(X_0=1) = 2/3$, what is $\mathbf{p}(n)$?
