Time Scale Creator PRO7.1

Database coordinators: Jim Ogg, Felix Gradstein

Software development: Abdullah Khan Zehady, Nag Varun Chunduru, Palem Gangi, Adam Lugowski, Aaron Ault

TS Creator is for you to create on-screen and downloadable charts of any portion of the geologic time scale with your choice of bio-, magneto-, chemo- and other events in Earth History.
TSC Pro can load and modify data and has expanded graphic routines.
See HELP for Features.

Reference time scales, visualization and chart system

Tour and Exercises using external Datapack

“*TimeScale Creator*” is a time-scale database with visualization software-package in JAVA (which should work on most platforms; see FAQs for solving problems). This version is the current phase of our dream of a general portal to Earth history, plus user-generated charts. Most of the datasets are oriented toward geologic history, but we include a demo datapack with some aspects of human civilization.

This *Tour and Sample Exercises* is oriented toward a general audience.

What it does:

- (1) **Screen display** of user-selected time-span and selected columns of geologic time scale information (stages, paleontology, magnetics, sea-level, chemistry, impacts, other planets, etc.). You, the user, can change the vertical-scale, column widths, fonts, colors, titles, ordering, range chart options and many other features. Mouse-activated pop-ups provide additional information on columns and events.
- (2) **Save** the final graphic as a SVG (scalable vector graphics) or PDF file for direct import into Adobe Illustrator or other common drafting software. You can also save your “settings” to recreate the charts on-screen.
- (3) **Upload additional datapacks** of regional geology and transects, high-resolution isotopes, ancient cultural episodes, etc.; plus create and upload your own datasets. The **Pro** version, after uploading such datapacks, allows you to save the associated graphic files and to re-save merged datasets. See “*About Pro*” on the website for details, plus additional datapacks.

Internal Database (*approximately 50,000 event-ages in this version*):

There are over 300 stratigraphic columns grouped into categories, mainly spanning the past 550 million years (the era with animal fossils) of Earth’s history. All events are calibrated to "A Concise Geologic Time Scale 2016" by J.G. Ogg, G.M. Ogg and F.M. Gradstein (Elsevier, 2016). You can download a full listing of columns, plus the main references, from the website.

THIS INTRODUCTORY TUTORIAL:

This suite has 3 parts:

- (1) How to use TSCreator and hands-on tour of some of its features (ca. 30 minutes)
- (2) Examples of datapacks with additional features (evolution, map-interfaces, etc.) (ca. 30 minutes)
- (3) Using the on-line chart-delivery versions (TSC-Lite) (ca. 15 minutes)

Part 1 – Using the main TSCreator

How to use it: *(a simple step-by-step tutorial; see the extensive Manual.pdf for more features)*

First, if you haven't already downloaded the program, go to <https://engineering.purdue.edu/Stratigraphy/tscreator/index/index.php> (which mirrors to a server at Purdue University's College of Engineering) and install either the .exe (for Windows) or the .jar (JAVA for most platforms). If you have a problem with the program under Windows or Mac, then you may need to update or install its JAVA – see link on the download page of the website. **You need Java 8 to run TSCreator 7.2**

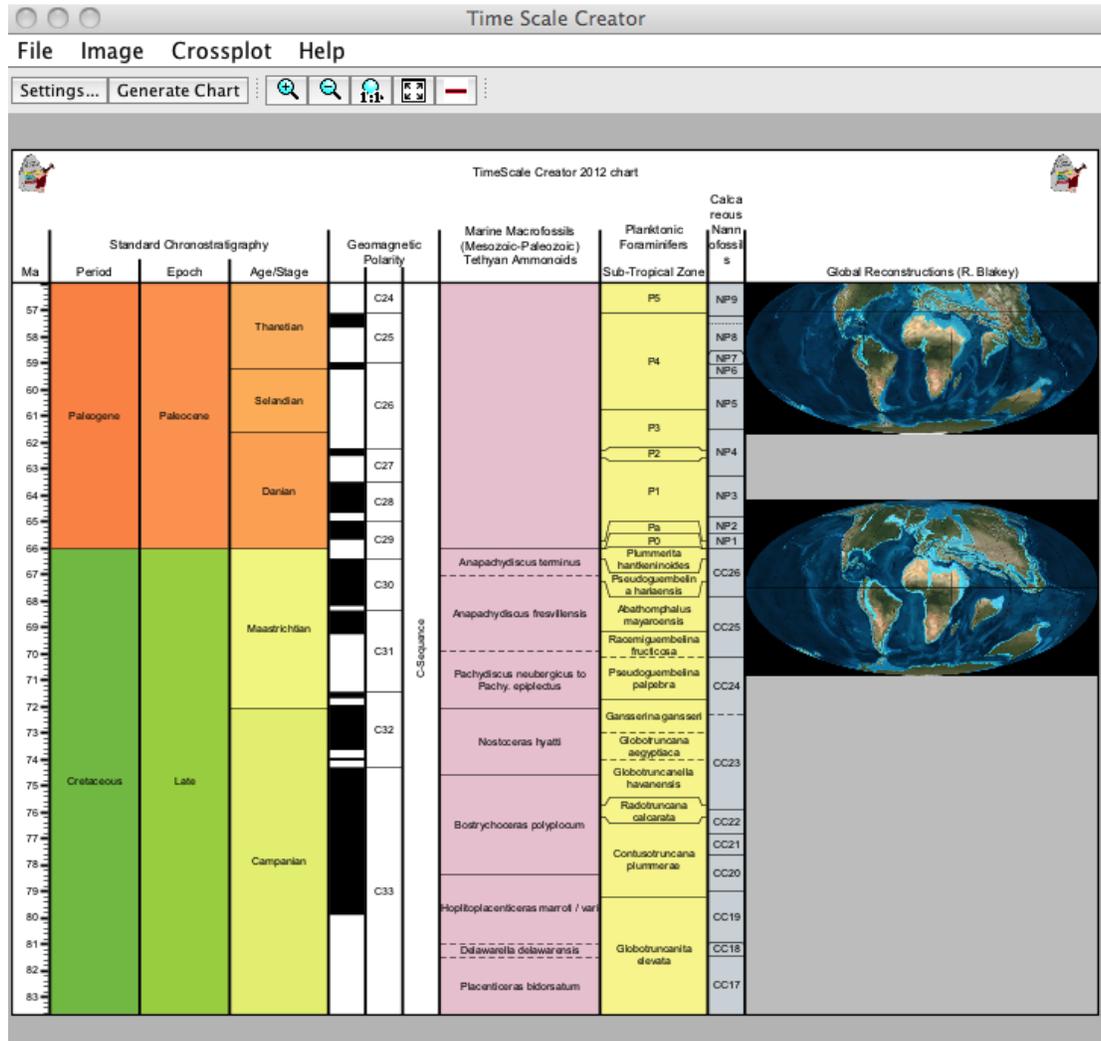

Tour #1 -- Default settings

- (1) **Begin** the program by double-clicking on the *TS-Creator.jar* or *TS-Creator.exe* icon.
- (2) **An opening screen window** with our data-providers appears, and the internal database is automatically loaded (~60,000 data lines of event-ages and curves). Stretch this window to fill your particular screen size, because this will determine the “fit to window” size of the output graphic display.

[NOTE: The default screen display is independent of the actual diagram, but you can rescale the image to actual size. The saved SVG graphics will be scaled according to the scales set by you, and will not be the sizing that you initially see on the screen.] Advanced users can go under the File-menu to append external databases or replace the default suite. We will give examples under the Part 2 (using “datapacks”) below.]

- (3) Click “**Generate**”. A message about “*Rendering*” should be displayed. The default run takes about 10 seconds. The image is a part of the Neogene (ca. 2 to 15 myr ago) with the initial default set of zonations – international divisions of geologic time, magnetic polarity chrons, major planktonic foraminifer and calcareous nannofossil zones and global reconstructions. This is just a sampling of the array of biologic, geochemical, sea-level, magnetic and other information that has been cross-calibrated by a generation of earth scientists. In the supporting databases (a separate array, with output that is mirrored in this software), the age of all these events are computed according to their observed or statistical occurrence relative to each other, to astronomical-climate cycles and to radiometric-age control. If one calibration is changed, or an age is updated, then all events that depend upon that calibration will also automatically adjust; therefore, new charts can be quickly produced. It is not real-time, yet – the relational databases do not directly feed into values within the visualization system – but this will come in the near future.
- (4) **Age-control:** Click the “*Settings*” button. This opens a new window. There are 4 tabs. Begin with “**Choose Time Interval**”. For your first adventure, set the “*Top of Interval*” as “**Thanetian**” stage (55.96 Ma at top), and the “*Base of Interval*” as “**Campanian**” stage (83.64 Ma at base). *[Notice that you can also designate the Top/Bottom of the interval in millions of years.]*

(5) Click “**Generate**”. The image now includes ammonites zones of Tethyan Realm. For each time-interval within the Phanerozoic, the default-on sets generally include the primary biological reference scales.

Tour #2 -- User-selected stratigraphic columns and other options

Now, suppose we wish to plot planktonic foraminifer datums and named global sequences through the late Campanian through mid-Paleogene (75 Ma to 60 Ma).

- (1) First, click the **Choose Columns** tab of the **Settings** window. The available stratigraphic columns are indicated. For now, we will turn OFF the Ammonite columns.
Open Marine Macrofossils (Mesozoic-Paleozoic). Then **open Ammonoids**.
 The blue-box for *Tethyan Ammonoids* is checked “on” – Click this highlighted box to **OFF**.
- (2) **Close** the directory of *Marine Macrofossils (Mesozoic-Paleozoic)*; and **Open Standard Chronostratigraphy** (top of directory listing).
 Click the box **ON** next to the *GSSPs* to activate that column. This will display which stages have international-ratified basal definitions or Global Stratotype Section and Points (“GSSP”). Close the directory.

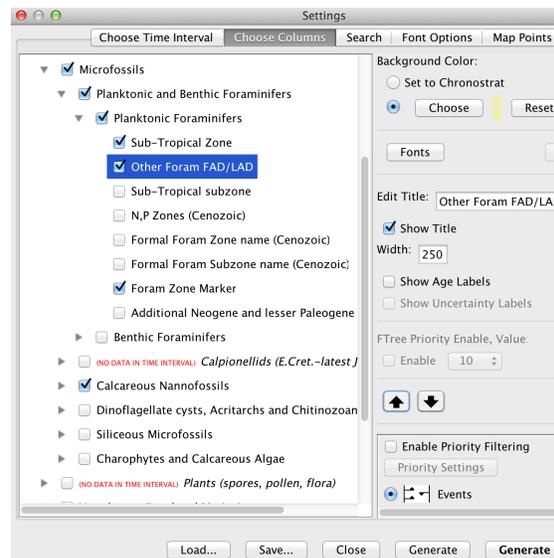

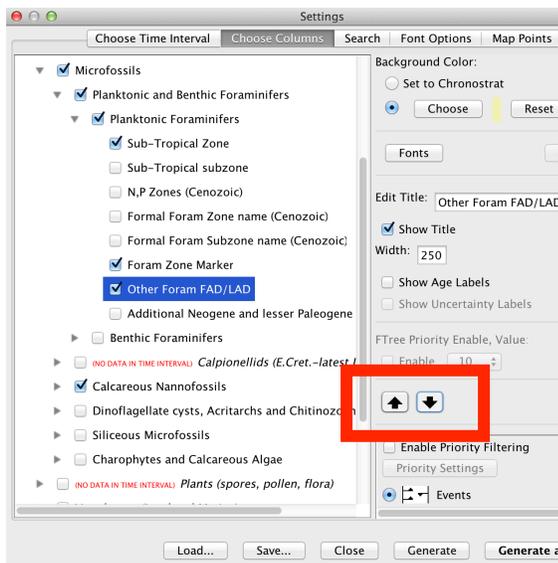

(3) Next, **open** the directory *Microfossils*, then the sub-directory *Planktonic and Benthic Foraminifers*, then sub-sub-directory *Planktonic Foraminifers*. Highlight the name *Planktonic Foraminifers*, and notice that the main selected sources of data appear in the lower-right box.

Click the boxes **ON** next to *Foram Zone Marker* and *Other Foram FAD/LAD*. Notice on our screen display that the column for *Sub-Tropical Zone* was too narrow to adequately display the full zone genera-species names.

Highlight the name *Sub-Tropical Zone* – a set of options appears on the right panel. In the middle is “*Width*”, which has a default of **120**. Change this to **150**, followed by a Return to activate that choice.

Notice that you can also change the title of the column (*by typing in that window*), font sizes, direction of labels, move the column relative to adjacent ones, change background color, show age-labels, and other options. We will explore these later.

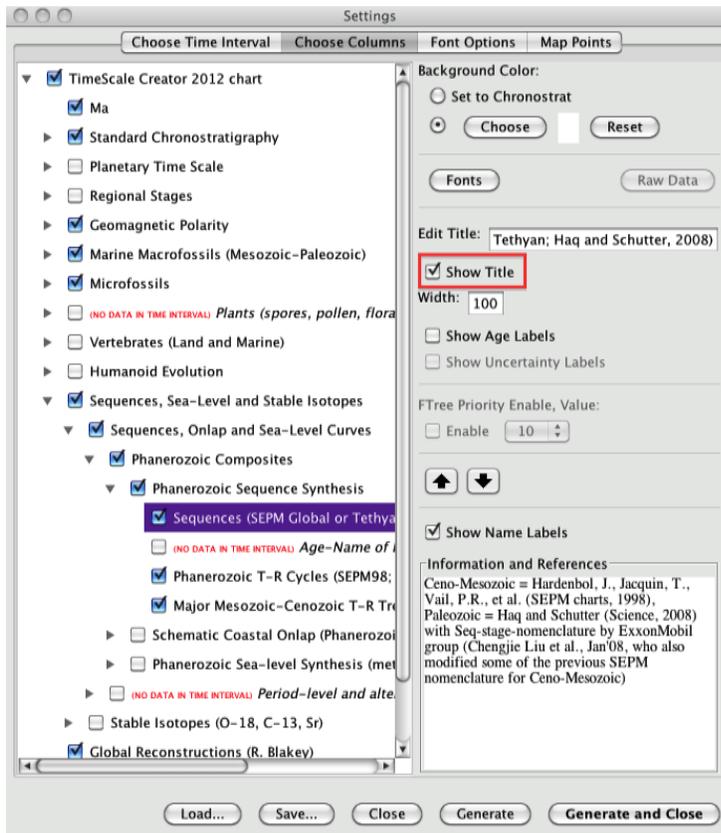

Let’s say you want the *Other Foram FAD/LAD* column next to the *Sub-Tropical Zone* column: Highlight *Other Foram FAD/LAD* and then move it upward with the arrows. You can move all the sub-directories up or down inside their directories.

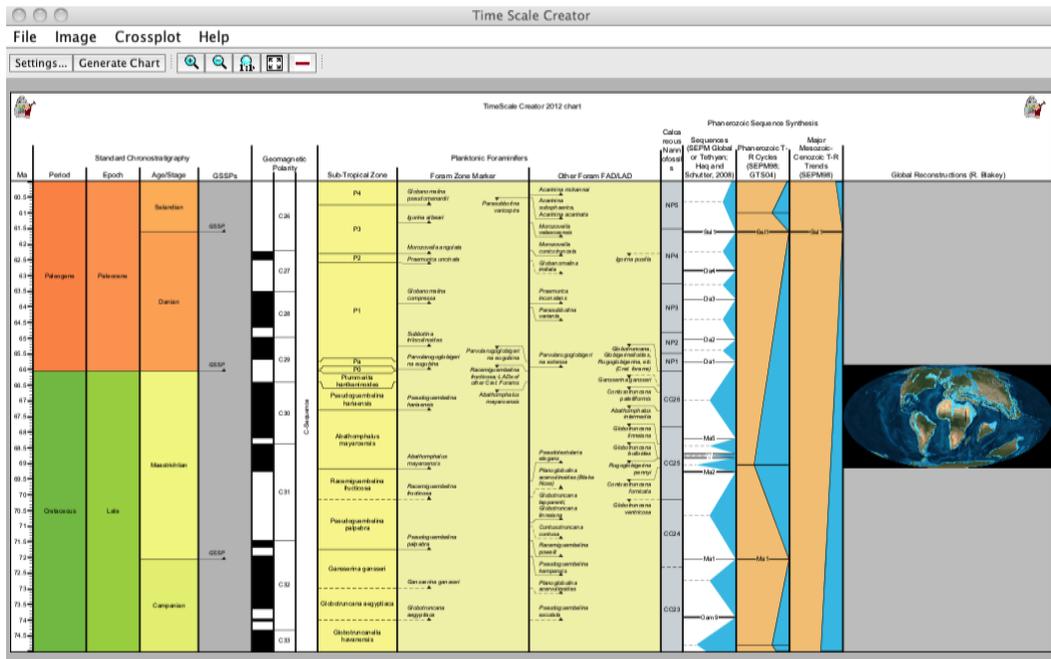

(4) Similarly, turn **ON** *Sequences (SEPM Global or Tethyan; Haq and Schutter 2008)*, which are the major sea-level changes. This column is located in the *Sequences, Sea-Level and Stable Isotopes* directory
Sequences, Onlap and Sea-level Curves sub-directory
Phanerozoic Composites sub-subdirectory
Phanerozoic Sequence Synthesis
Sequences (SEPM Global or Tethyan; Haq and Schutter 2008)

To avoid excessive column labels when we are displaying only a single column within a larger suite the “*Show Title*” box (middle of the right-hand menu of options) is unchecked in the upper 3 directories.

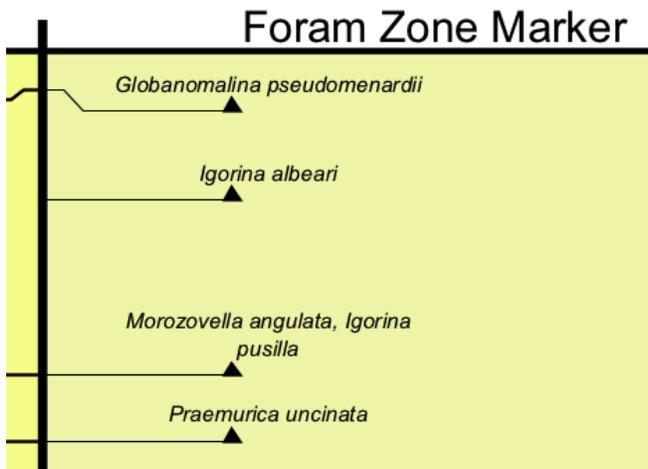

Highlight *Phanerozoic Sequence Synthesis* and see that the “*Show Title*” box is selected.

- (5) Now, we want to select the time interval and enlarge the vertical scale.
 Click the “**Choose Time Interval**” tab at TOP of Menu window. Click **ON** the *Millions of Years* option for the Top of Interval, and enter **60**.
 Then, click **ON** the *Millions of Years* option for the Base of Interval, and enter **75**.
 Set the underlying vertical scale to be **2** cm per 1 myr on printed page (rather than the default of 1 cm per myr).
- (6) Click **Generate**. Depending on your screen size, it will be possible to read the names of the different planktonic foraminifer species that appear or become extinct through this time interval.

- (7) To see this information easier, you can either use the Magnifying or Reducing icons on the upper menu, or use a bit of magic – While continuously pressing down the CONTROL key on the keyboard, hold down the left-button on the Mouse (on Mac; on some Window's versions, it is the right-button) and sweep over the region that you wish to display on the screen. You can use the side-bars on the display to pan over the magnified image. To return to the full display, either use the Reducing or 1:1 icon or fill-screen (right-icon of the box with arrows) as needed, or tap the **Generate Chart** again.

Tour #3 – Pop-ups, Internet access, and selected display options

(1) **Hot-Mouse**

Now, return to the “*Choose Time Interval*” menu under *Settings*. At the bottom, click **ON** the *Add MouseOver info*. This will activate pop-up windows of additional information.

(2) Click the *Choose Columns* tab, and open the sub-directory with the *Sequences (SEPM Global or Tethyan)*.

Sequences, Sea-Level and Stable Isotopes directory

Sequences, Onlap and Sea-level Curves sub-directory

Phanerozoic Composites sub-subdirectory

Phanerozoic Sequence Synthesis

Sequences (SEPM Global or Tethyan; Haq and Schutter 2008)

Highlight the name “*Sequences (SEPM ...)*” to bring up options on the Right panel.

Click ON “*Show Age Labels*” (just below the *Width* box). **Generate**.

(3) Notice that all Sequence boundaries now have tiny age-labels next to the displayed names. One can display such ages for any selected zone or datum columns.

Move your Mouse-pointer over Sequence boundary “Ma5”. As you put the Mouse-pointer over the name “Ma5”, notice a red rectangle. Click directly on the text “Ma5”, and a window will appear with information on the calibration of this sequence boundary.

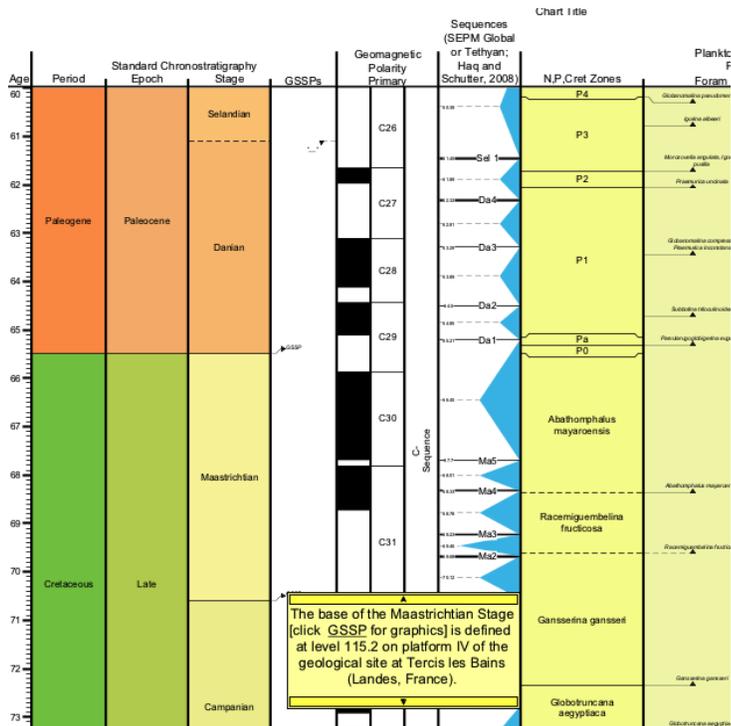

Now, move the Mouse-pointer over the column title “*Sequences (SEPM Global or Tethyan)*”, and a new pop-up window appears with the source of information. This “MouseOver” option is currently installed for all Column headers (either major or minor), Sequence boundaries, and most of the Planktonic Foraminifer and Calcareous Nannofossil zones and datums. Eventually, we will try to provide such background information and hot-links for the other thousands of items.

(4) **Internet links** – Move your Mouse-pointer over the title “*Standard Chronostratigraphy*”. A red rectangle appears. Click on the title, and another window will appear that says:

“[International Commission on Stratigraphy [ICS](#). Click [Geol. TimeScale Foundation GSSP](#) for boundary (GSSP) definitions, status and nomenclature.]”

Click on the active-phrase “[Geol. TimeScale Foundation GSSP](#)”. Your default browser will be activated and an Internet site will be opened that has tables of the definitions of all international divisions of the geologic time scale (middle of the orange-background top menu).

Now, back to the **TimeScale Creator** display -- click on the GSSP arrow next to the base of the Maastrichtian Stage. Another window will open, which says “[The base of the Maastrichtian Stage [click [GSSP](#) for graphics] is defined ...]”. When you click on that [GSSP](#), then an Internet site will open with a description and links to location map and outcrop graphics. You can click on the thumbnail (upper-right) to see a summary graphic of that GSSP.

We will see even more of how this system acts as a gateway to other data stored around the world in Part 2 of our suite of tours.

- (5) **Saving Display Parameters** -- If you create a screen display that you like, then under *Settings*, there are bottom-buttons that enable you to **SAVE ...** a "*Settings file*" that contains most of the necessary instructions for your current TimeScale Creator chart, or to **LOAD ...** an earlier one to re-generate that same graphic for an audience or for additional revisions. If you are working on a major diagram, then we suggest using this feature to periodically save intermediate graphics, just in case the operating system has problems.

Details on the many other capabilities and display options are illustrated under "Features" in the Help menu (main window).

Exercise – Global Warming

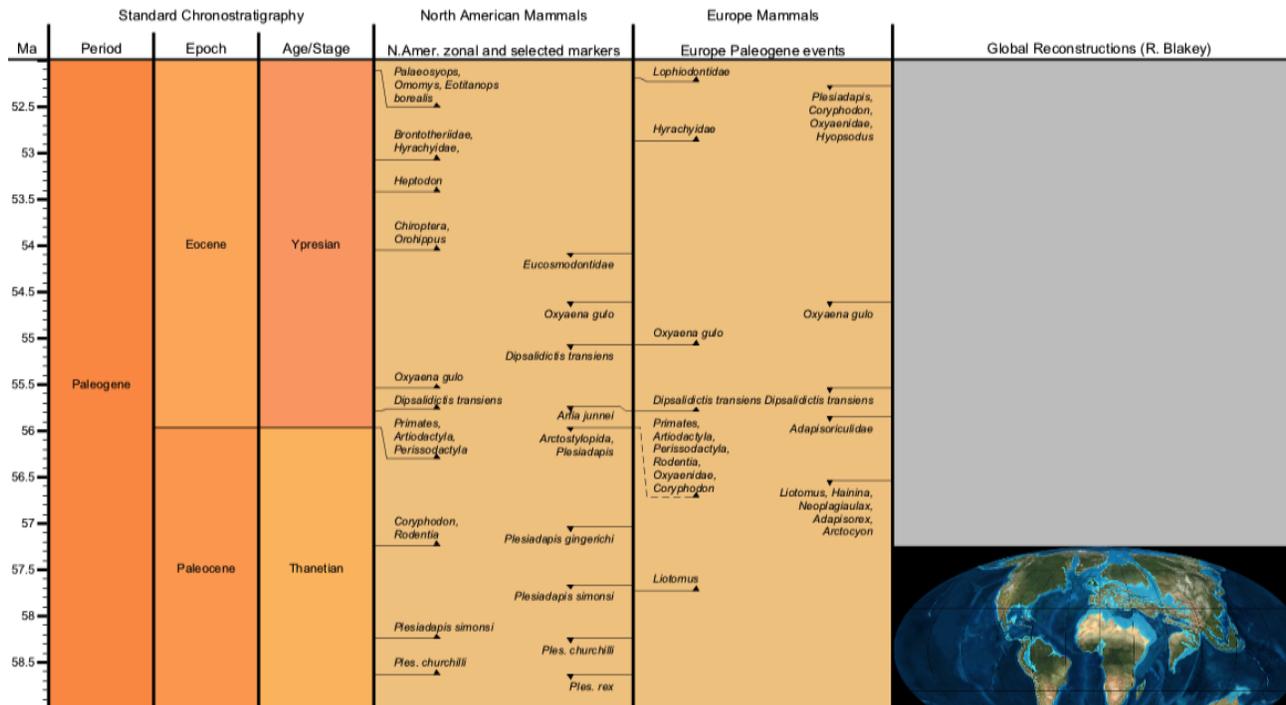

- (1) **Resetting display; then focus on Paleocene/Eocene boundary interval**

Under FILE (top-left of menu bar); click "Replace Data with Default Datapack". This will clear all your settings.

Set up a diagram with the following: **Age** (use manual entry, and be sure to click that option) = (52 Ma top) to (59 base); **vertical scale** = 3; **Geomagnetic Polarity** – turn OFF; **Microfossils** – turn OFF.

Under "*Vertebrates (Land and Marine)*", turn ON **Mammals**, then **open** the appropriate subdirectories to turn ON **N.Amer. zonal and selected markers** (only, turn off the other sub-columns), **and**, under Europe, turn on ONLY the **Europe Paleogene events**; and turn **OFF** all other Mammal columns.

Generate.

(2) Under both North America and Europe Mammals, you will see that the first appearance of **Primates** (early apes) occurred near the base of the Eocene epoch.

Earlier in North America (57.2 Ma), you see that **Coryphodon** (browsers that looked like a hippopotamus) and **Rodentia** (the family of mice and rabbits) appeared; but in the Europe column, these did not appear until the same time as Primates.

Look closely at the reconstruction. The only way for animals to walk between North America and Europe was via land bridges from Asia to each continent in the latitudes of the Arctic-circle. Hippopotamus-like animals could not survive such Arctic temperatures IF it was a world like today. Plus, there is the appearance of Primates -- Primates in the Paleocene-Eocene, like their relatives today, are tropical creatures. These Primates could not thrive in North America and Europe if the climate was like today (*until their human descendents arrived with warm clothing*).

Let us investigate this question: **What enabled these appearances of American-mammals (Coryphodon, Rodentia) within Europe at the beginning of the Eocene, and the ability of Primates to thrive on both continents?**

(3) Let's look at climate indicators. First, to save space, turn OFF **Global reconstructions**, but remember what that diagram told us.

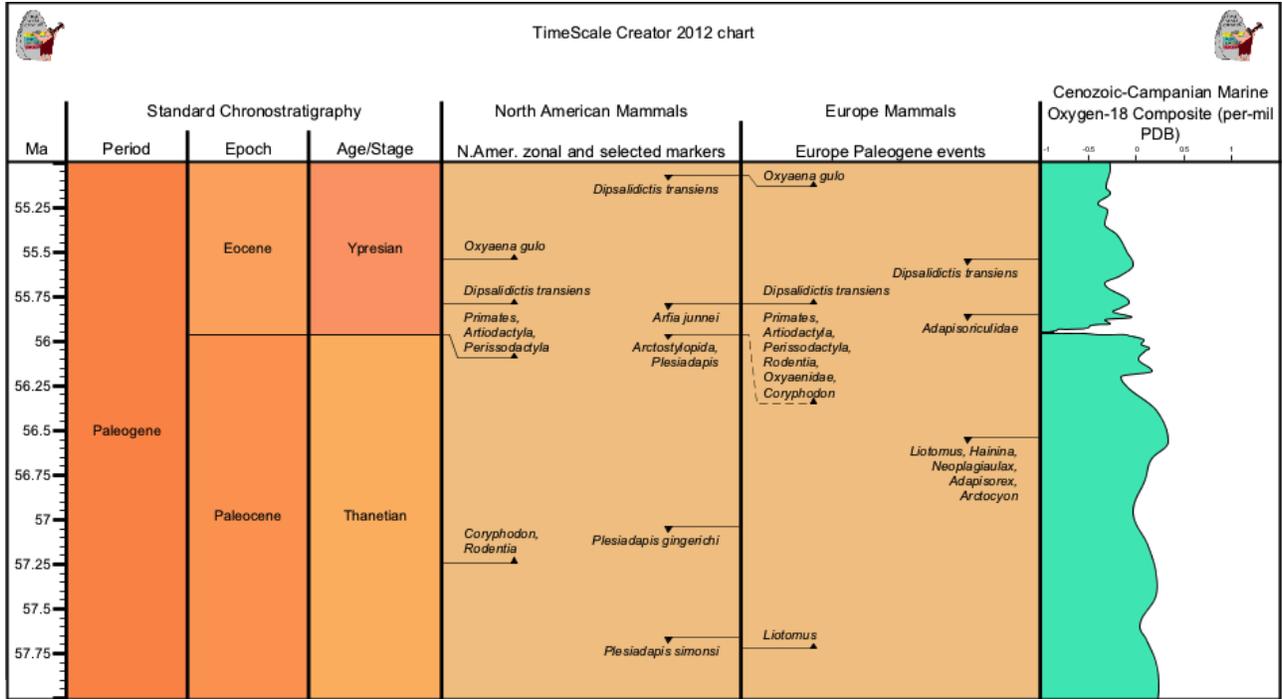

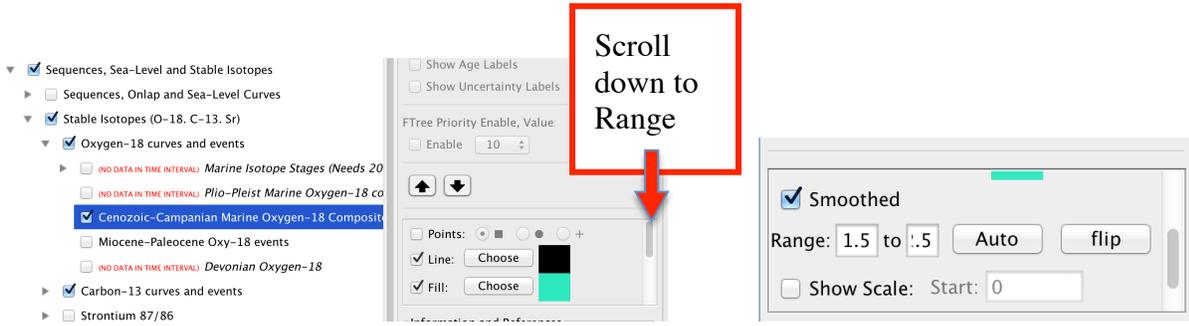

Make the Time Settings to be **55 to 58 Ma**; and Vertical Scale as **5**.

Under **Sequences ...**, turn **OFF Sequences, Onlap and Sea-level Curves**, turn **ON Stable Isotopes**, open this sub-directory and **Oxygen-18 curves and events**, and be sure that the **Cenozoic-Campanian Marine Oxygen-18 Composite** column is ON.

Highlight the name **Cenozoic Campanian Marine Oxygen-18 Composite** to bring up the menu of display options.

Scroll down and Change the **Range** (currently -1.5 to 2.5) to be (-1.0 to 1.5); and click **Show Scale** (and make Step as 0.5). To enlarge the scale, click the **FONT button**, and change the 6 to an **8**.

Generate.

Oxygen-18 is a monitor of deep-sea temperatures, and helps indicate the temperatures in high-latitudes where these deep waters form. In an Antarctic-ice-cap-free world (which was the Eocene situation), an Oxy-18 value of “0” corresponds to a temperature of about 10°C, and a value of “1” is about 6°C.

To help you see these temperature trends more clearly we will underlay the Oxy-18 plot with a gradient background.

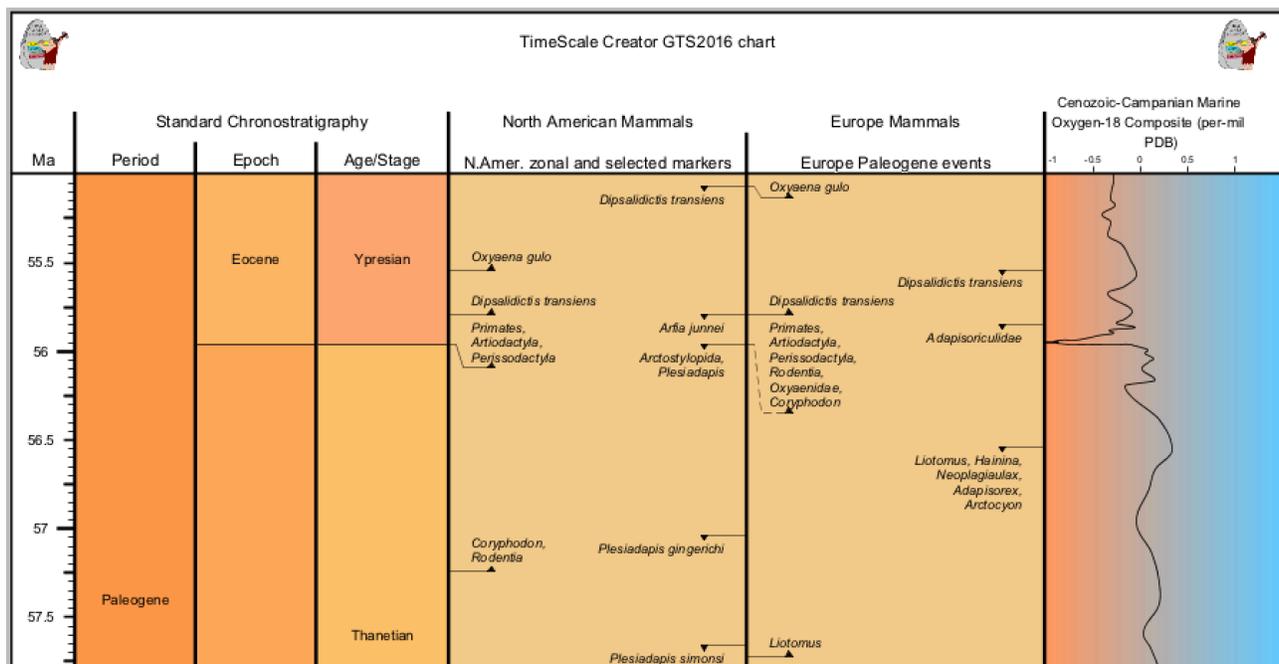

Go back to **Settings** and **Highlight** the name *Cenozoic Campanian Marine Oxygen-18 Composite* again. Now turn off the **Fill** button in the menu and scroll down to select **BgrndGrad** (Background Gradient) and choose a color for the left side (warmer side) of the plot. Then do the same for the right side (colder side).

Information and References
 Derived from Cramer (2009) -- See Saltzman and Thomas (GTS2012 Carbon-isotope chapter); but only every 10th item from 9-point averaging of Benthic foraminifer compilation (29000 data points in original) is shown here; NOTE: Cramer had two sets -- original and "adjusted" (which removed many of the original)

Hit **generate** and you should get the following chart:

(4) This is interesting. Think about the plot, and answer the following:

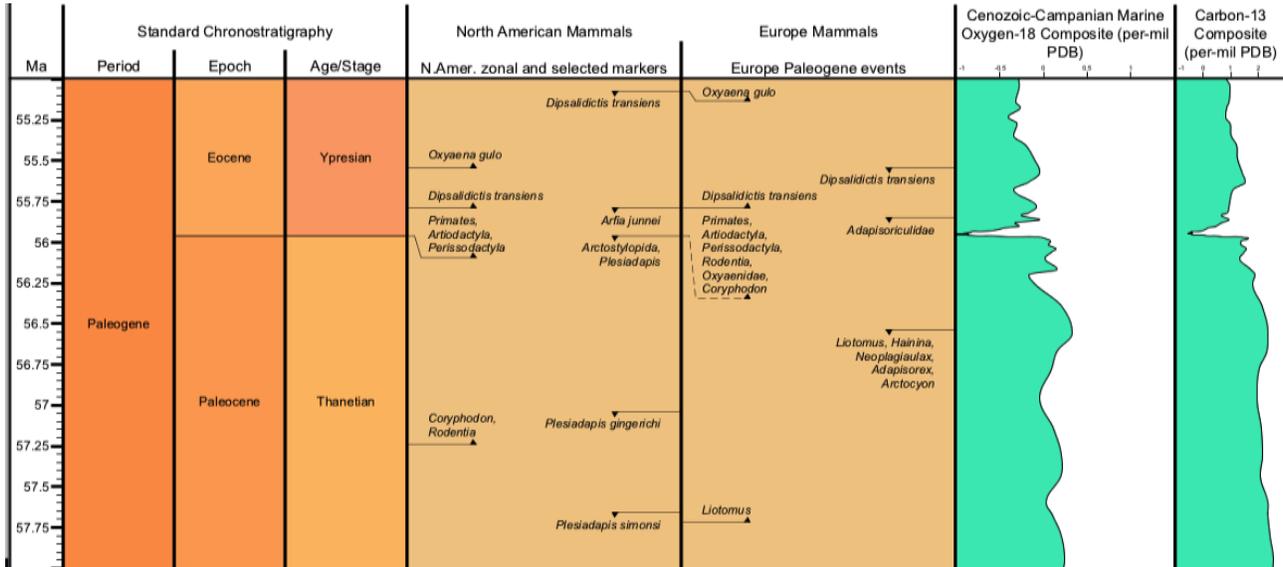

- *What was the general temperature trend of deep-waters from 58 million-years-ago until the base of the Eocene?*
- *What happened to bottom-water temperature at the time that Primates appeared in North America and Europe?*
- *What does this imply about the changing climate at that time?*

(5) Now, what may have caused this?

Under **Sequences** ..., then under **Stable Isotopes** --> **Carbon-13 curves and events**, turn **ON** the **Cenozoic-Mesozoic Marine Carbon-13 Composite**.

As we did with Oxygen, highlight the name *Cenozoic Marine Carbon-13 Composite* to bring up the menu of display options. Change the Range to be (-1 to 3); Show Scale (and make Step as 1). Turn OFF *Carbon-13 and Anoxic Events*.

Generate.

(6) Carbon-13 of organic matter is Negative, because life prefers to use Carbon-12. This is also true for coal and oil, which are derived from organic matter. Therefore, if the global-ocean becomes more “*negative*”, then it means that the organic carbon is being recycled back into the Earth system (especially the atmosphere) or that another source (volcanic eruption gases and/or methane) is pumping new “light” carbon into the atmosphere/ocean. A negative shift in the Carbon-13 value by 1 is nearly equivalent to doubling the Earth’s carbon-dioxide through release of stored organic-carbon.

- ***Therefore, when you look at both the carbon and oxygen, what might have happened at the base of Eocene?***
- ***What were the implications for mammals on the continents of North America and Europe? Think about those “normally cold” high-latitude land bridges.***
- ***This event marked the emergence of modern mammals. Given that coincidence, then what might happen with future global warming?***

(7) **Possible contributing cause.**

The bottom directory in *Choose Columns* menu is *Impacts, Volcanism, Tectonics*. Turn it ON; then open it to turn **OFF** *Impacts* and **ON** *Large Igneous Provinces*.

Under the *Choose Time Interval* menu, turn **ON** *Add MouseOver info (popups)*.

Generate

This episode is known as the “**Thermal Maximum**” of the past 70 million years. The reasons for the ultra-high greenhouse and carbon-release are still debated, it appears that a phase of the massive volcanic event “North Atlantic Volcanic Province” that began at the Iceland volcanic center and released carbon-dioxide was one of the initial triggers. As the ocean began to warm, the warmer deep waters may have de-stabilized methane hydrates (which have *very negative* carbon-13 values) in the sediments, and the potent methane greenhouse gas accelerated the warming feedback. This is explored if you click the pop-up, then its link to “LIP of the Month 08aug” at Largeigneousprovinces.org.

Tour #4 – Obtaining ages of events and using SEARCH

There are three ways in TSCreator to obtain the numerical age of events, zones or other items. For this exercise, we will use the Tethyan calcareous nannofossil, *Tribrachiatulus orthostylus*, which has a short range in the Ypresian stage of early Eocene. Our question is what is the age of its first-appearance datum (FAD) and last-appearance datum (LAD).

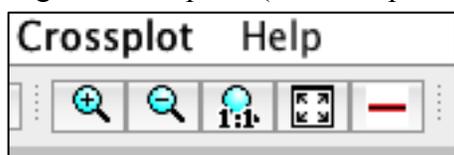

(1) Using horizontal guide line

Reset the TSCreator display using “**Replace Data with Default Datapack**” under the File menu (under left button on uppermost menu bar). Select a time interval that is only **Ypresian** (base to top) with a vertical scale of 3. Use “**Add MouseOver**” option.

Turn on the **Tethyan Nanno Zone Marker** column (under Microfossils). Generate.

The LAD of *Tribrachiatulus orthostylus* is the defining event for the NP12/NP13 zonal boundary, and its FAD occurs in the upper part of NP10.

Turn on the RED guide line option (icon at top of display):

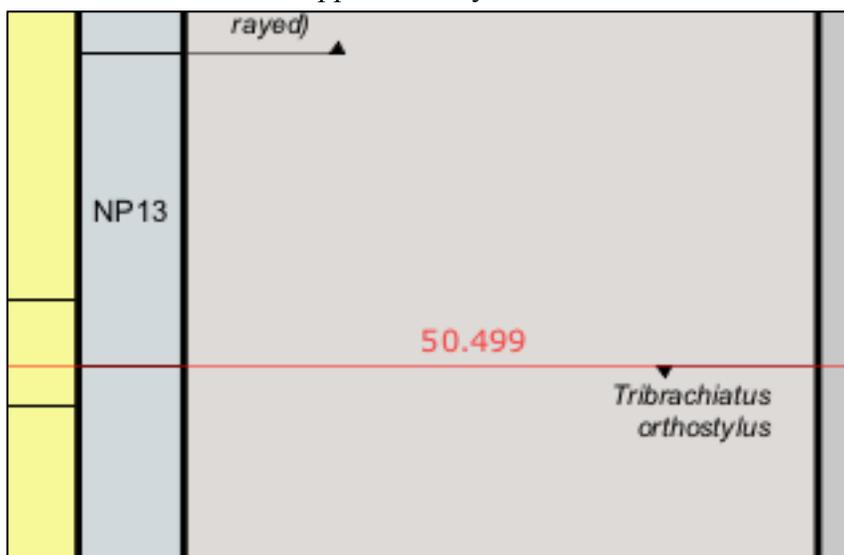

This activates the guide line, until the red-icon is again clicked off.

Position the line over the LAD. The age of the line position is displayed in Red-font to 3-decimals; but the ability to move this line is constrained by the pixels of your screen display.

NOTE: A single-click when the red-line is activated will LOCK that line, until clicked again. This is useful when having zoomed into a large diagram and you wish to see what other events are coeval – lock the red-line and move the diagram sideways with the scroll bars.

We see that the LAD is approximately 50.50 Ma:

Do the same for the FAD of *Tribrachiatulus orthostylus*. It is about 54.4 Ma.

You can click on the taxa name to get a popup explaining some of the published calibration logic. At the bottom of each popup is a hot-link to Nannotax (Univ. London) that provides details and images for the selected fossil.

(2) Using “show ages” display

Turn off the red-line option.

You already did this “show ages” briefly for Sequences, but we now wish to apply it to our particular fossil.

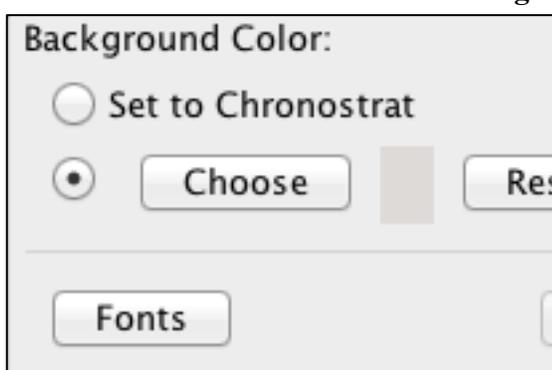

In the settings menu, highlight the *Tethyan Nanno Zone Marker* column. In the column-option menu to the right, click ON “Show Age Labels”. Do the same for the *NN,NP,CC,NJT,NT Zone* column. Generate.

The display now has small numerical ages attached to each nannofossil FAD/LAD and your NP zones.

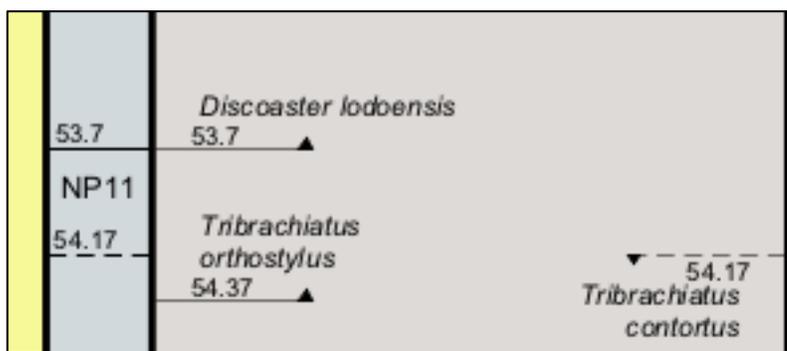

The default font is small to avoid clutter, but let’s now make these numerical ages larger.

Back to the Settings, and highlight the *Tethyan Nanno Zone Marker* column again.

Click the “Fonts” button that is below the **Background Color** at top of right menu:

Activate the “Age Label:” option set which currently has Arial 6 as the font. Increase this to Arial 10. Do the same for the NP column. Generate, and the numerical age labels are now easier to read:

The ages in this option are displayed as 2-decimals. You also have options to make these in a different color.

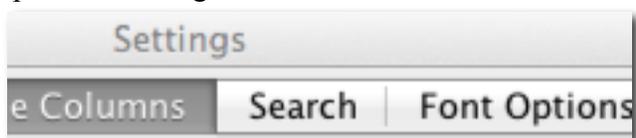

So, from this method, what are the FAD/LAD ages for *Tribrachiatum orthostylus*?

NOTE: You can also use the “Font Options” at the top of Settings menu to set a default for the Age Labels of all columns at once, however if you’ve set these for an individual column (as we just did) then your column-setting overrides the general default.

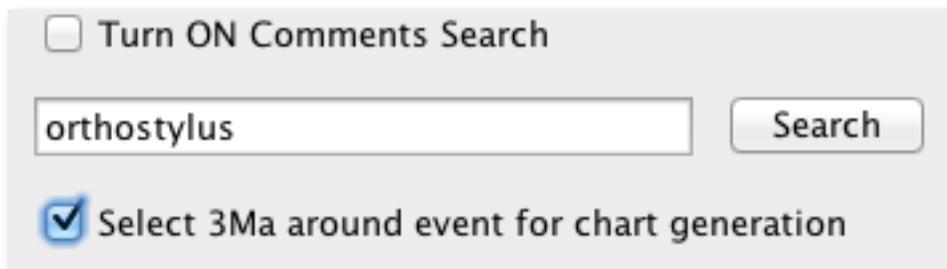

NOW, do a Reset using “**Replace Data with Default Datapack**” followed by Generate to make the default chart. We’ll now look at a very elegant method.

(3) Using SEARCH (TSCreator Pro version only)

At the top of the Settings menu is a Search button:

Open Search, and we'll input the last name of our nannofossil, plus turn **ON** the "Select 3Ma around event for chart generation":

Tap "**Search**" button, and you receive (1) full name of the taxa and type of column in which it is found (e.g., *Tribrachiatulus orthostylus* was found only in an Event column in our case), (2) The partial name of that column (e.g., Tethyan Nanno Zone markers – but only the first part is shown), (3) the numerical Age, (4) the type of event (LAD/FAD, etc.), and the option to see the popup for this item.

This immediately gives us our desired age information without needing to find the items in the chart.

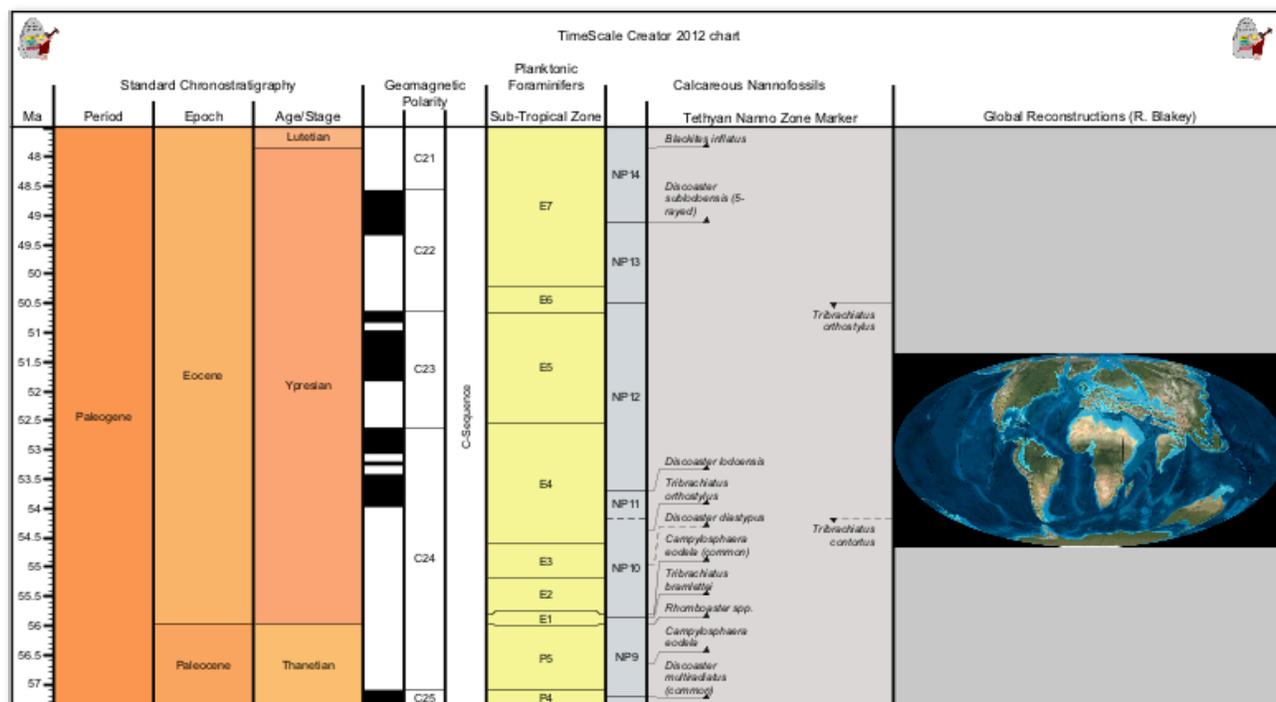

However, we can also generate a custom chart that shows these "in context" with 3 myr added to the top/bottom limits.

Click **ON** "Add to Chart" for the LAD and the FAD of our fossil:

Tribrachiatulus orthostylus – Event				
Add To Chart	ColumnPath	Age	Qualifier	More Info.
<input checked="" type="checkbox"/>	Tethyan Nanno Zon...	50.5	LAD	Additional Info
<input checked="" type="checkbox"/>	Tethyan Nanno Zon...	54.37	FAD	Additional Info

Click Generate, and voila!

The Search has automatically turned on the Tethyan Nanno Zone Marker column, set the age span as 3 myr above the LAD of *Tribrachiatulus orthostylus* to 3 myr below its FAD and made the scale as 2 cm/myr.

Other Search options

You can use “*” as wild characters to search for all names of events, zones, etc. that have that partial string.

Prof. Dr. Hans **Gocht** at University of Tübingen was an expert on dinocysts, and some were named after him. Input “**Gocht***” (with asterix at end) into the Search. Hit Search.

In this case, the search returns species (e.g., *Wetzeliella gochtii*) and genera (e.g., *Gochteodinia*) in different columns. Use the scroll-bar on the right to see the other entries.

Let’s see what one of these look like.

At the top, for *Wetzeliella gochtii*, click the “Additional Info” button.

Additional Info

○ ○ ○ Comments - *Wetzeliella gochtii*

Additional Info

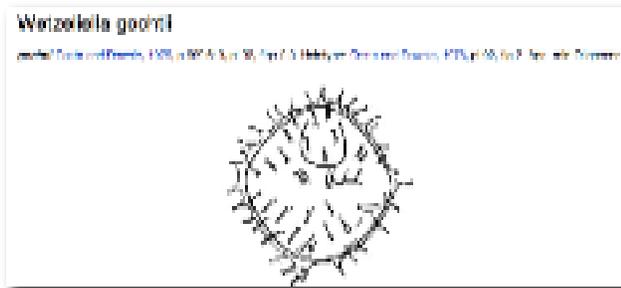

Additional Info

Additional Info

Additional Info

Priority(10=Highest) = 10; Comments: [For details click [Wetzeliella gochtii](#)]. CALIBRATION = Base of N22 on GTS04 diagram. Pre-2012 TSC version of GTS04 = 1/8th up in Chron C12r (or Base of Nanno Zone NP22)

This returns “Priority” (an option in datapacks for avoiding cluttered displays, which will be explained briefly in the presentation; and the default is “10”), and the Comments associated with this fossil and its calibration. Click the [Wetzeliella gochtii](#) hot-link, and **Dinoflaj** will open in a browser to provide a drawn image of this dinocyst:

If desired, one can always see its placement within a TSCreator chart by clicking “Add to Chart”, and the appropriate columns will be automatically activated.

In this way, one can search the TSCreator internal (or added external) datapacks to locate columns with desired fossil taxa, zones, lithologic formations and other items; obtain the numerical ages; and in many cases, use the “additional information” to activate links in the popups to external servers to provide more information without even generating a single on-screen chart.

Feel free to play with this Search system before we go to the next parts!

Part 2 – Using Datapacks (with evolution displays, map-interfaces, etc.)

Now, let's use *TimeScale Creator* to explore some interesting geologic events:

Datasuite #1 – Mappacks, and Oil in Australia and in North Sea

We will first use an Australia datapack, then a British one

(1) **Resetting display; Downloading and adding Australia Datapack**

Under FILE (top-left of menu bar); click “**Replace Data with Default Datapack**”. This will clear all your settings.

At the TSCreator <https://engineering.purdue.edu/Stratigraphy/tscreator/index/index.php> website, under Datapacks menu, scroll down and open the tab for “*Australia*”, read the description, and **download** (*save, ideally to the desktop for easy opening*) “**Australia Mappack**”. This joint product with Geoscience Australia contains lithologic columns for all major Australian basins for the past 2.5 billion years, plus all major biostratigraphy zonations and sets of tectonic reconstructions (a total of nearly 500 columns!). We will use only a small portion.

In TSCreator, use **FILE** (upper-left of top menu) to **Add Datapack**, and add this Australian one. It will take a few moments to load, because there are nearly 500 columns!

Choose Time Interval of **140** to **180** Ma; with vertical scale of **1**.

First, we will turn OFF our previous column sets –

Under **ChooseColumns**, turn **OFF** “*Marine Macrofossils (Mesozoic-Paleozoic)*”,
“*Microfossils*”, and
“*Global Reconstructions*”.

Also, turn OFF “*Geoscience Australia – Biozonation Datapack*”.

Turn **ON** “*Geoscience Australia – Lithostratigraphy of Phanerozoic Basins*”.

Under this *Geoscience Australia – Lithostratigraphy of Phanerozoic Basins*, open “*Greater NW Shelf*” to turn ON “*NW Australia tectonics*” and “*Bonaparte Basin*” (and turn off all other basins).

Now, go to Settings, click “**Map Points**” (upper-right button on top menu), which will open a set of maps.

Click the Australia base map (top one). Bonaparte Basin is at the top, with a submap at the leftmost square. Click it to open that sub-map.

We want only the *Petrel* and *Vulcan* sub-regions -- when you hover your mouse over a dot, then a pop-up will tell you the name. The *Petrel* and *Vulcan* should be “green”, and click off (*turn white*) the other sub-regions. Close these map windows.

Generate.

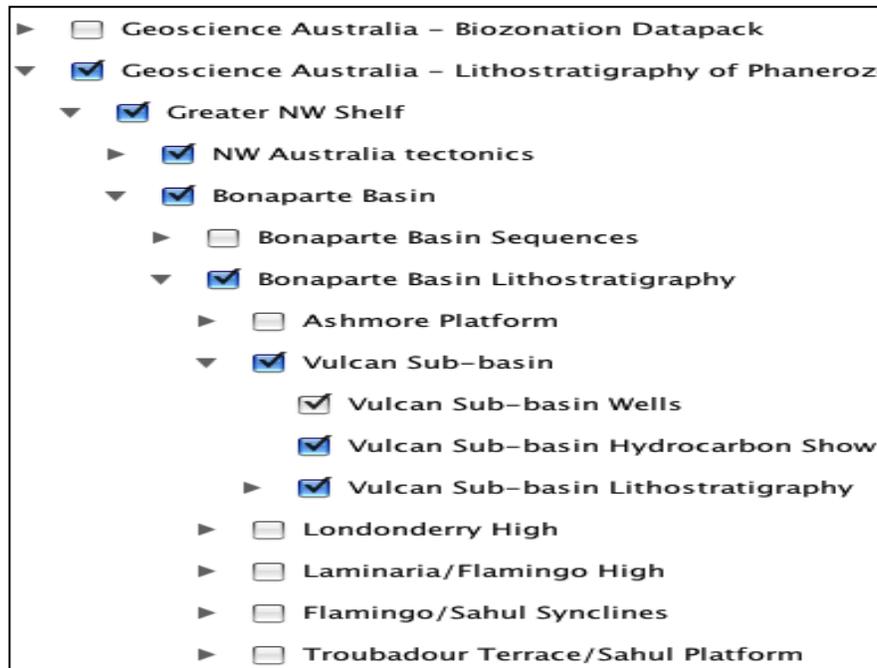

[GENERAL NOTE: If you get a warning of “Don't Panic” after Generate, then try Generate Chart again. Sometimes JAVA, especially the Windows version, doesn't clear its memory usage very efficiently. SEE LAST PAGE for details.

On some Windows operating systems, you may need to completely close the JAVA to free its memory usage, and restart the program. You will notice this problem if the program becomes slower and slower to display charts.]

(2) Offshore NW Australia oil-gas field example

This is a display of the geology in offshore Northwest Australia, an area that is becoming a major gas-oil exporter to China and other regions. What you see are sands (*dotted-yellow*) and dark-clays (*dashed brown*). Columns next to these changes in rock types with time displays levels with discoveries of oil (*green* symbols) and gas (*red* symbols). The clayey Frigate Shale and Lower Vulcan Formations are organic-rich source rocks for these Jurassic oil-gas reservoirs. The oil-gas migrated both up (into Upper Vulcan) and down (into Montara Formation).

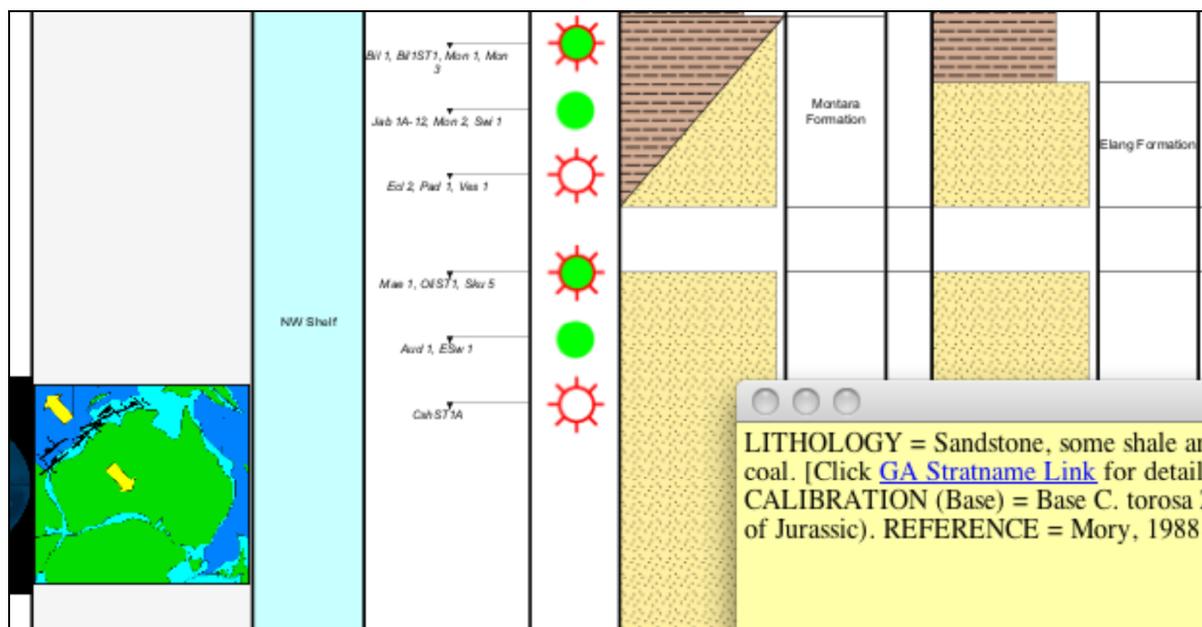

Let's get some additional information. Using the "Choose Columns" menu under Settings, open Bonaparte Basin, then Bonaparte Basin Lithostratigraphy subdirectory. Open "*Vulcan Sub-basin*" sub-subdirectory, and turn ON "*Vulcan Sub-basin Wells*".

Under the main "*Choose Time Interval*" of Settings, active "**Mouse-Over**".

Generate and click on the Bonaparte-Basin title. In the pop-up window, click on the basin report. This opens a website at Geoscience Australia, and a summary of that basin is presented. You can click on geologic summaries, sub-basin location maps and other items. EXPLORE ... (At the moment the Australia website is changing, therefore some of the links don't work)

Now, back to *TimeScale Creator* – use the mouse to click on one of the rock units. Clicking on its internal hot-link sends another request, in this case as a search-call to their Oracle database for information on the rock formation. [Below is a "*simplified*" version (many of the oil-gas wells are removed for clarity).]

Try this with one of the well-names, and access a separate Oracle database of well reports. The tectonic column (the “light-blue” one) events are linked to FrOG Tech summary reports on each episode. Try clicking “NW Shelf”. *[NOTE: FroGTech is revising their website, therefore this link might be inactive at times.]* In this fashion, the on-screen display is a “GATEWAY” via geologic age into information stored on the Geoscience Australia and other computer databases.

(3) Offshore NW Australia oil-gas field example

Let us look at why there was this change from dark shales to sands.

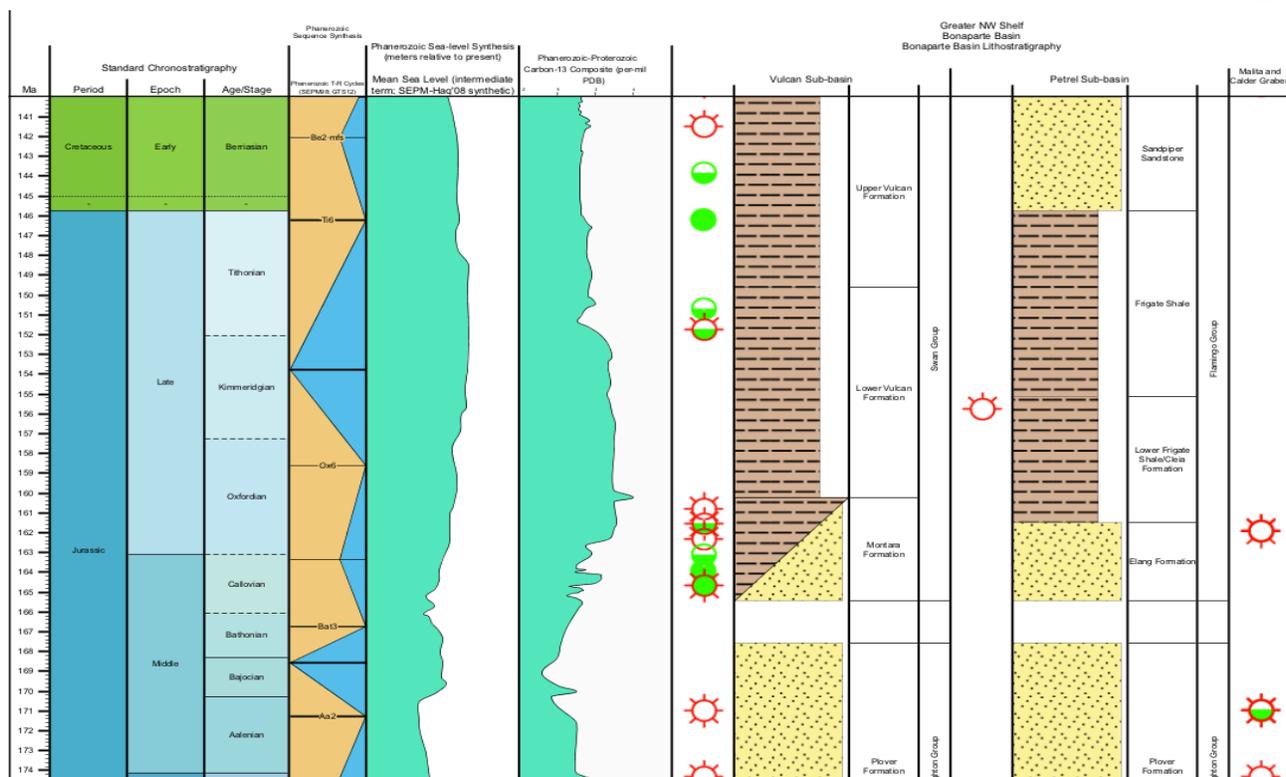

To save space, turn **OFF** *Vulcan wells, NW Australia tectonics, and Geomagnetic Polarity*. Turn **ON** *Sequences, Sea-Level ...* directory, then open its *Sequences, Onlap and Sea-Level Curves* sub-directory, turn off *Phanerozoic Composites* sub-subdirectory, turn on *Period-level Sequences* subdirectory. Select *Jurassic – SEPM98*

The T –R Cycles show a cartoon of global sea-level changes, in which the Blue-color indicates rising/falling ocean levels.

Turn **ON** the *Phanerozoic-Proterozoic Carbon-13 Composite* (in the *Stable Isotopes directory, Carbon-13 curves and events* subdirectory); then, scroll down and turn ON Show Scale (with Step as 2).

Generate.

[Below is a partial version (with vertical scale set to 0.5 to emphasize trends).]

- **What was sea-level doing during the formation of the Frigate Shale?**
- **What was it doing during the Sandpiper Sandstone or Upper Vulcan?**

A major sequence boundary near the Bathonian-Callovian boundary corresponds to a “gap” in the accumulation of sands on the NW Australia shelf. This suggests a global lowstand of sea-level exposed the shelves in many regions, and it is considered a major sequence boundary.

- (4) **Carbon balance and sea-level.** A rising sea-level enhances the trapping of clays and the accumulation of organic material on continental shelves. The buried organics contain a greater proportion of “light” C-12 (relative to “heavy” C-13) than the ratio in seawater. Therefore, the seawater undergoes a relative enrichment in C-13, which is recorded in carbonates. In the plot above, C-13 increases to the right. The rise of Carbon-13 is during the Callovian through early Oxfordian (peaking in mid-Oxfordian) as the sea level was undergoing a long-term rise and flooding onto global shelves.

In NW Australia, the main pulse of clay-rich sediment accumulation was during the Kimmeridgian, when sea-level was near its peak. These clays partially capped the migration of hydrocarbons from the underlying organic-rich deposits of Oxfordian; therefore some of the oil-gas may have accumulated in the underlying sands.

- (5) **Was this unique to Australia?**

Let’s find out, by adding Britain, half-way around the world.

First, turn **OFF** *Petrel Sub-basin*, and also turn OFF our *Isotopes* column.

From the TSCreator website, download from *British Isles* the

“***BritishMappack_Public_GTS2016_15July2016.mdpk***”. **Add** this to your set – this British suite will be at the bottom of your Columns listing. Go to the **Map-points interface**, and

activate Britain location map from the **World Map** (top of set). Use this map to turn off the columns other than **North Sea (S)** and **Hampshire** basin. **Generate**. Wow, this is fascinating.

- ***What was sea-level doing during the formation of the Kimmeridge Clay?***

In the early part of Late Jurassic, the British region of North Sea saw a change from underlying sand-rich or carbonate-rich sediments into the Kimmeridge Clay. This, just like the Australian Lower Vulcan Formation (!), is also an organic-rich claystone, and is the source-rock for the famous North Sea oil-gas fields.

As in Australia, some of this oil-gas migrated to fill the underlying sands –further north, these “Brent Group” sands are the reservoir for one of the first major North Sea fields to be developed in the mid-1970s.

Then, when sea-level retreated toward the end of the Jurassic, river deltas built outward and dumped their sands onto the continental margins (Petrel sub-basin of Australia’s Bonaparte Basin and Britain’s Hampshire Basin; but an interval of non-deposition in southern North Sea). Some of these river-delta deposits also became the future oil-gas reservoirs that received the maturing hydrocarbons from the underlying organic-rich clays.

The combination of a rising global sea-level and burial of organic-rich sediments during the “Oxfordian-early Kimmeridgian” time, followed by the deposition of sands or other shallow-water deposits during the latest-Jurassic drop in sea-level led to the oil-gas riches of other regions, including Saudi Arabia and Siberia. This mid-Late Jurassic is an unusual interval of Earth’s history – such a vast quantity of carbon was buried around our planet during the rising and cresting global sea-level.

[NOTE: If you have been loading and replotting datapacks continuously to this point, it is recommended that you Exit TSCreator, and re-start it “fresh”. This will clear the memory usage by JAVA. Otherwise, the next image-heavy suites may cause the JAVA system to slow or even stop.]

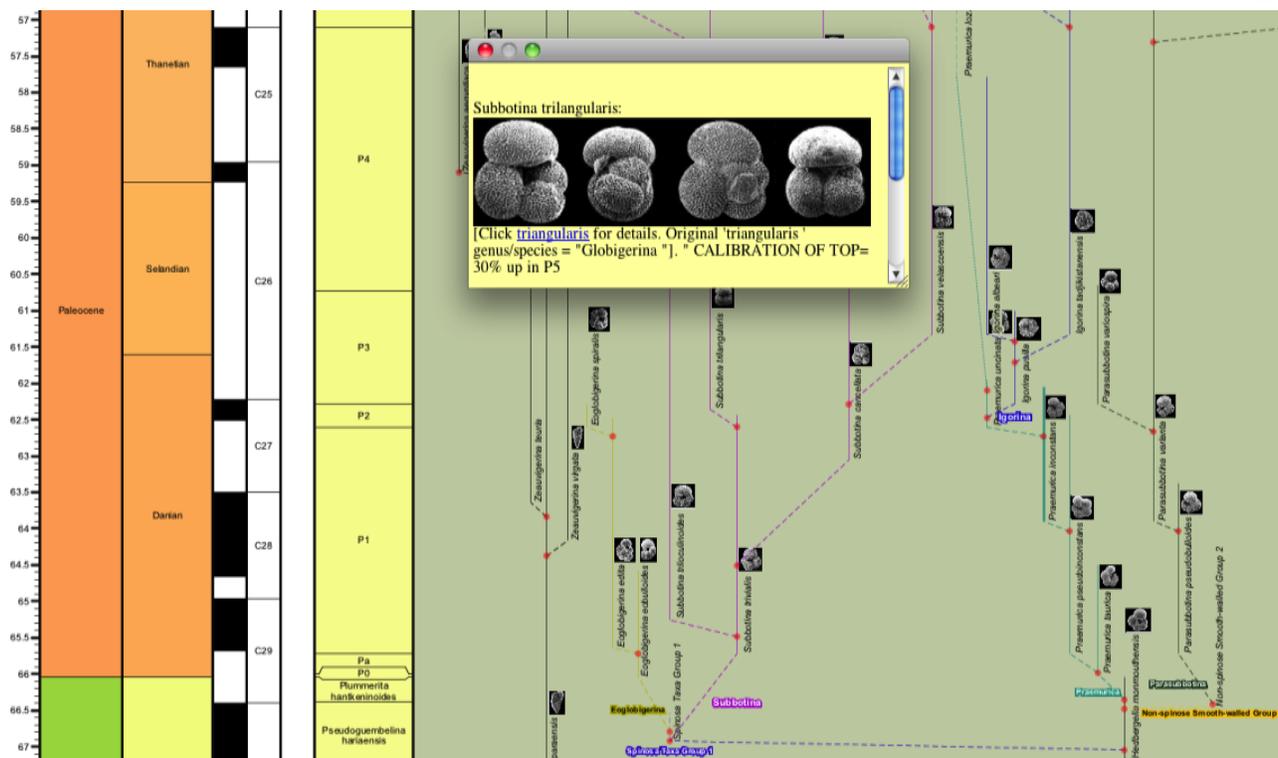

Datasuite #2 – Evolution of Paleogene Planktonic Foraminifers

(1) Resetting display; Downloading and adding Foram-Evolution Datapack

*If you haven’t started TSCreator “fresh”, then under FILE (top-left of menu bar); click “**Replace Data with Default Datapack**”. This will clear all your settings.*

At the TSCreator <https://engineering.purdue.edu/Stratigraphy/tscreator/index/index.php> website, under Datapacks menu, open the tab for “*Planktonic Foraminifer Evolution through Paleocene-Eocene*”, read the description, and **download**

“*PaleogeneForamsEvolution_GTS2016_July2016.dpk*”. This joint product with C. Liu contains a branching evolution model for the diversification of planktonic foraminifers during Paleocene-Eocene (after their near extinction at end-Cretaceous).

In TSCreator, use **FILE** (upper-left of top menu) to **Add Datapack** for this one. Choose Time Interval of **40 to 70 Ma**; with vertical scale of **3**.

Turn ON **Add Mouse-over**.

First, we will turn OFF some of our default column sets -- Under **Choose Columns**, turn OFF “*Marine Macrofossils (Mesozoic-Paleozoic)*”, “*Calcareous Nannofossils*” (which is under *Microfossils*), and “*Global Reconstructions*”.

Generate

(2) Pop-ups and links

The screen is filled as TSCreator fits the entire chart to your window. Therefore, to explore this set, click “1:1” or other Zoom (menu of display option buttons at top-left).

The range of each foraminifer species is shown, plus its inferred evolutionary branch from its parent. The thumbnail images give a general view; but if you click onto the Foram name, then a pop-up opens with a much larger image:

Click on *Globigerina officinalis*, the one in the upper-left of the suite. This has a larger image with 3 views. The popup gives calibration information, plus a “Click **officinalis** for details” – click, and a browser window should open to the appropriate taxonomy page for this species as hosted at Chronos by that Paleogene-Eocene working group. Close the pop-up.

Now, use a **RIGHT**-mouse click (WARNING – ONLY RIGHT-CLICK at this point) onto the RED-DOT (node) at its branch from its parent (inferred to be the long-ranging *Subbotina roesnaesensis*). A window opens with the calibration of the branch. Close the pop-up. Now, on that same node, use a **LEFT**-mouse click, which will collapse that branch of *Globigerina officinalis*. The image re-generates, and it automatically returns to the *approximate* zoom-setting and position. The Red-node is now flashing, indicating that there is a hidden branch.

(3) **Priority settings, and Conserve space**

Return to SETTINGS menu (Choose Columns), and Highlight the “*Paleogene Planktonic Foraminifer Evolution*” column. The set of display options to the right includes “**FTree Priority Enable, Value:**”, which is default-off with “10”. Set this to be **ON**, with value of **8. Generate.**

Click 1:1 display-button, and scroll around the new chart.

We had assigned “priority” values to the individual foram ranges/branches such that only the “main parents” are shown. These arbitrary “main parents” were given Priority setting of 10 or 9; secondary branches a priority of 7; and single “end-twigs” a priority of 5 or 3.

If you click on a blinking node at this high-priority-only chart, then its full-detail branch will open up. Try it.

These priority-display options can be installed for any set of zone, event or range/evolution datasets.

If one draws an evolutionary-diagram by hand, then it is common to draw “new” branches reaching over “dead” ones. This space-saving option is also available in TSCreator in a simple form.

On the “*Choose Time Interval*” of the Settings menu, at the bottom are special options.

Click the “**Conserve Chart Space in Family Tree Plotting**” option, and **re-generate** your Foram Evolution chart. You should see that the horizontal scaling becomes much more compact. Try changing the Priority setting of the highlighted “*Paleogene Planktonic Foraminifer Evolution*” to a lower value, such as “4”, and re-generate to see this display method.

Rise and Fall of Pyramid-builder Civilization

Oxygen isotopes in Ice Cores

At the TSCreator <https://engineering.purdue.edu/Stratigraphy/tscreator/index/index.php> website, under Datapacks menu, open the tab for “**Past 10,000 Years**”, download **Past10000yr.txt**.

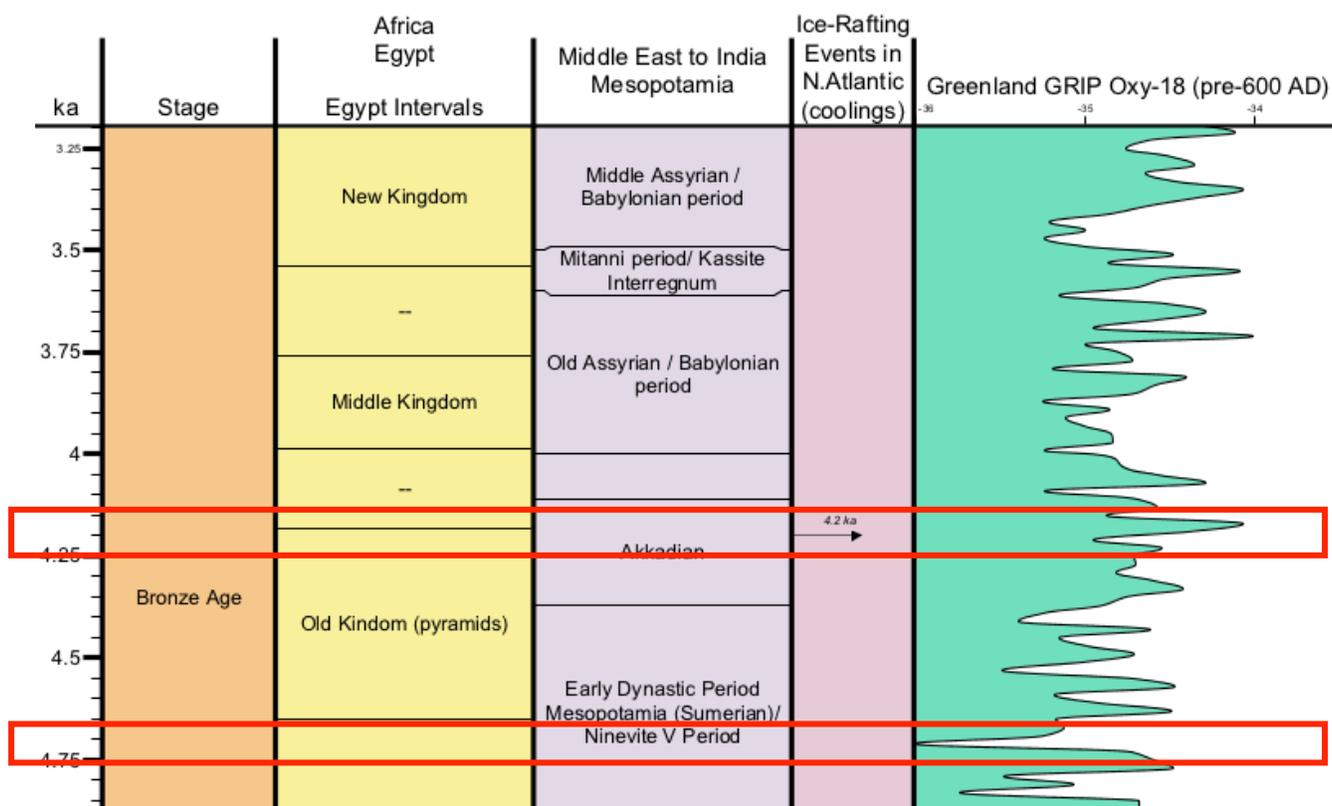

- (1) Load Human Civilization time scale – Under FILE, click “***REPLACE*** Data with Datapack”, and find/load the file “**Past 10000 years.txt**”.
This replaces the geological scales with a new one of selected archeology and ice core information. This database has been compiled from both archeology sources and the independent international drilling of Antarctic and Greenland ice cores. *[NOTE: it is only a preliminary sketch of what will become a major dataset in the future.]*
- (2) Under Settings, choose the interval spanning the Bronze Age (3.2 ka top; 5.5 ka bottom); and a **vertical scale of 8**.
Under **Choose Columns**, turn OFF everything, **except** Age, Stage, Egypt, Egyptian Intervals and Middle East to India – leave these ON. **Generate**.
- (3) Notice that the end of the Old Kingdom (pyramids) is close to the end of the Akkadian civilization in Mesopotamia; and there is a gap before the Middle Kingdom and Assyrian. Let us see what may have caused this.

Let’s use oxygen-isotopes from Ice Cores from Greenland and North Atlantic ice-rafted debris episodes to see what may have caused the rise and sudden fall of the Pyramid dynasty.

- (4) In Settings, click ON *Ice-Rafting* and *Greenland GRIP Oxy-18*. Highlight the name *Greenland GRIP Oxy-18*, and activate the *Show Scale* (scroll down) with a Step of **1**. **Generate**.

Let's use oxygen-isotopes from Ice Cores from Greenland and North Atlantic ice-rafted debris episodes to see what may have caused the rise and sudden fall of the Pyramid dynasty.

- (4) In Settings, click ON *Ice-Rafting* and *Greenland GRIP Oxy-18*. Highlight the name *Greenland GRIP Oxy-18*, and activate the *Show Scale* with a Step of 1. **Generate**.

Background:

See diagram above, where dramatic events in human history are marked in red.

NOTE: A **decrease** in Greenland Oxygen-18 (*hence more Oxygen-16 in the snow fall*) is a shift to **LEFT** in the diagram. The Scale is -36 (**left**) to -34 (**right**)

A **colder** climate in Greenland is associated with a greater “snow-out” of moisture before the storms reach the center of its ice-cap (from where the ice-cap was drill cored). Oxygen-18 is progressively removed during snowfall; therefore, the remaining moisture reaching central-Greenland is more depleted in Oxygen-18 (more negative in values). A Decrease in Greenland Oxygen-18 is a shift to **LEFT** in the diagram, therefore is interpreted to imply that Greenland became colder. It is thought that the cold episodes that affected Greenland probably affected the entire northern hemisphere, including the region of Egypt and Mesopotamia.

In contrast, a Greenland **warming** (more Oxy-18 in the snowfall; a shift to the **Right**) is sometimes associated with a surge in glacial icebergs, causing “Heinrich” levels rich in ice-rafting debris further south in the North Atlantic.

THE RISE OF EGYPT PYRAMID DYNASTY

- (a) What direction (*increase* or *decrease*) did Greenland Oxy-18 isotopes change near the beginning of the Old Kingdom?
- (b) From the relationship of temperature to oxygen-isotopes in Greenland ice, what does this imply about the Northern Hemisphere temperature?
[GIVE YOUR LOGIC]
- (c) Assume that this same trend in temperature happened in Egypt for its summers. Then, what would have happened with the summer monsoon rainfall? Why?
- (d) What is a possible scenario for why the Old Kingdom of Egypt developed at this time? **[GIVE YOUR LOGIC]**

THE FALL OF EGYPT PYRAMID DYNASTY

The end of the Old Kingdom (pyramids) at about 4200 years ago (“4.2 ka”) is simultaneous with the end of the Akkadian civilization in Mesopotamia. There is a gap (anarchy) before the Middle Kingdom in Egypt and rise of Assyrians in Mesopotamia.

Let’s again use oxygen-isotopes from Ice Cores from Greenland to see what may have caused this.

- (e) What direction (*increase* or *decrease*) did Greenland Oxy-18 isotopes change at this “4.2 ka” event?
- (f) From the relationship of temperature to oxygen-isotopes in Greenland ice, what does this imply about the Northern Hemisphere temperature?
[GIVE YOUR LOGIC]

(g) Assume that this same trend in temperature happened in Egypt for its summers. Then, what would have happened with the summer monsoon rainfall? Why?

(h) What is a possible scenario for why the Old Kingdom and Akkadian empire simultaneously collapsed? *[GIVE YOUR LOGIC]*

TODAY

(i) Now, if you were in modern Egypt or Iraq, would you prefer global warming, or a cooler climate? *[GIVE YOUR LOGIC]* *[It is an interesting question for climate policy.]*

NOTE on this 4.2 ka event. We invite your speculation “from what you’ve learned” or other ideas. This is still controversial. Indeed, IF this was a “typical Heinrich event”, then as documented by Bond et al. (1992), not only does the presence of left-coiling foraminifera *N. pachyderma* indicate the deep southward invasion of polar water during the time of an Heinrich event, but the drop in surface salinities was probably significant enough to temporarily shut down thermohaline circulation in the North Atlantic, thereby causing another type of cooling episode in the North Hemisphere.

The “4.2 ka” ice-rafting event seems to correlate with a temporary surge of cold-climate or arid-climate indicators in some regions; but flooding in others (e.g., China). Therefore, paleoclimate geoscientists are actively working to decipher what actually happened to Earth’s climate and the reason for the collapse of major civilizations at this dramatic time!

NOTE: One can also input datapacks using “Replace” in units of “meters” or other unit for stratigraphic outcrops and cored holes. If one has flagged the scale of a datapack in units other than “Ma”, such as “m” or “ft”, then it opens as a separate distinct set of columns separated from the other datapacks, or these can be cross-plotted against a geologic time scale for use in depth-age conversion.

This completes our tour of a couple of the many datapacks of TimeScale Creator – a visualization system for both built-in and external databases of Earth’s history.

Part 3 – TS-Creator On-Line (TSC-Lite)

Now, let's use a browser interface into new *TimeScale Creator* user-interfaces:

Internet-system – TSCreator “Lite”

(1) **Open a browser --** <https://engineering.purdue.edu/Stratigraphy/tscreator/tsclite/>

This may also be found as a Tab “TSC-Lite” at the top of the regular TSCreator website.

This TSCreator is initially intended for educational and general-audience usage.

(2) **Nannofossils – with Images and Nannotax links**

In the top menu, set ages to be **120** and **140**; and Vertical Scale to be **2**.

Turn on “*Enable Popups on Generated Chart*”

Turn on (turn Green) the red-dot on **Nannofossil zones**.

Generate; Click the 1:1 icon. Explore.

The result is similar to when one downloads the TSCreator datapack “Calcareous Nannofossils with Images” to “add” into the main TSCreator program. An advantage to the TSCreator server system is that many datasets can have active images for immediate delivery.

Click on any Nanno, and you’ll get a pop-up with larger images, plus a direct link to Nannotax for this species.

This system will work nicely on iPad, and even on iPhone – one can enlarge images with one’s fingers.

(3) **Dinosaur evolution – with Images and links**

At the top of the image, click “*Back to Chart Settings*”

For the age settings, use **110 to 200**, with a vertical scale of **0.5**

Click “**off**” the Nannofossils, and Click “**on**” **Mesozoic Reptiles** – this is the evolution of dinosaurs and their relatives. The full evolution of vertebrates is a very large datapack that can be downloaded for the full TS-Creator.

Click “**off**” the **Magnetic Polarity** and turn “**off**” **Reconstructions** (bottom of set)

Generate; Click the 1:1 icon. Explore.

The left-most set (with grey background) is a schematic evolutionary diagram. The other columns are ranges of selected dinosaurs and relatives of different groups.

Click on any range, and a pop-up appears with information (especially for the selected range sets). Many of these are also linked to external sites for more information.

As always, this is a work-in-progress.

(4) **Humanoids – with Images and links** (*if you wish to explore more*)

At the top of the image, click “*Back to Chart Settings*”

For the age settings, use **0 to 5**, with a vertical scale of **6**

Click “**off**” the **Mesozoic Reptiles**, and Click “**on**” **Humanoids** – this is the ranges of our ancestors, plus tool cultures.

Generate; Click the 1:1 icon. Explore.

The images (and links) are provided by the Smithsonian and American Museum of Natural History.

Our goal is to eventually have images for ALL fossil groups. Your contributions and assistance would be very welcome!

.....

Additional items -- Selected display options; “out of memory”, etc.

Saving Display Parameters (Settings) – Once you’ve created a screen display that you like, then under **Settings**, there are bottom-buttons that enable you to **SAVE ...** a “*Settings file*” that contains the necessary instructions for TimeScale Creator to recreate that display, or to **LOAD ...** an earlier one to re-generate that same graphic for an audience or for additional revisions. If you are working on a major diagram, then we suggest using this feature to periodically save intermediate graphics, just in case the operating system has problems. This setting option is also useful to standardize diagrams (fonts, arrangements, etc.).

Details on the many other capabilities and display options are illustrated under “*Features*” in the **Help** menu (main window).

Have fun exploring the data sets and graphic options, and we hope that you will find this suite useful for reference and generating base-graphics for your research and teaching.

NOTE: The free public TimeScale Creator does not allow you to save charts after a datapack has been added. Only the PRO version allows saving charts after uploading other datasets. See our PRO page for other features, and how to get the PRO version (which comes with a large selection of datapacks).

A word of advice during exploring – there are numerous close-spaced Foram and Nanno events in the Neogene in the current database (and an abundance of Sequences in the glacial-pulsed **Pleistocene**), so the auto-adjust software sometimes has problems to display these details unless a vertical scale of at least **4** cm per 1 million years. A similar high-density of detail occurs with the brief North American ammonite zones in the Campanian-Turonian interval and ammonite subzones within much of the Jurassic-Cretaceous. Therefore, we have placed some of this dense-detail into “additional” columns with the lesser-used secondary events, plus shorten the genera names for the ammonites and other taxa.

A MEMORY problem that may occur -- The default Java installation on some operating systems limits the amount of memory a program can use. This Java default may cause the program to occasionally display **out of memory** (especially with large or information-heavy displays after several iterations). **DON'T PANIC!** If this happens, a message will appear on the screen -- you can still save the *Settings* file to regenerate the on-screen display, and usually can save the non-displayed SVG graphic file to be opened in another graphics program or Firefox-type browser. If "***Out of Memory***" appears, then the *TimeScale Creator Pro* will also explain how to increase the Java memory allocation. In many cases, hitting “***GENERATE***” again will solve the problem! If that doesn't work, then before you restart *TSCreator* to clear Windows-memory, save your current settings (See above for SAVE/LOAD) to not lose much time.

In addition, on Window machines, the screen refresh will become slower and slower – again, the same JAVA problem in not clearing memory – so, save settings, then close and re-start JAVA and *TS-Creator* again.

We welcome your suggestions for major and minor improvements in the default database, visualization graphics, and overall system! Please convey your ideas, desires and critical evaluations to us at jogg@purdue.edu.

Database coordinator – **James Ogg**

*[professor, Dept. Earth & Atmos. Sci., Purdue University, Indiana; jogg@purdue.edu]
and Chair, Subcommittee on Stratigraphic Information, International Commission on Stratigraphy*

Visualization software developed by students of Purdue University
