Abstract

We develop a new continuum mechanics modeling framework, with particular focus on the van der Waals fluid. By invoking the microforce theory, the Coleman-Noll procedure is generalized to derive consistent constitutive relations in the presence of non-local effects. A new thermodynamically consistent algorithm for the van der Waals model is designed, based on a semi-discrete scheme using functional entropy variables and a new temporal scheme invoking a family of new quadrature rules. We show that the resulting fully discrete scheme is unconditionally stable-in-entropy and second-order accurate-in-time. Isogeometric analysis is utilized to implement the numerical scheme. The aforementioned properties are verified by benchmark problems. Finally, three sets of application problems are simulated to demonstrate the capability of the model and the algorithm. In particular, our methodology provides a comprehensive suite of predictive tools for boiling flows.

1 Introduction

1.1 Phase transition and classical modeling techniques

Liquid-vapor two-phase flows are ubiquitous in the natural world as well as in industry. Liquid-vapor phase transitions involve a sharp change of the fluid density, which is induced by environmental changes. Typical environmental changes include pressure variations and thermal variations. For instance, the local pressure near a rotating propeller may drop below the boiling pressure, and vapor bubbles may generate near the blades [1]. This phenomenon is called cavitation and is still a limiting factor for the ship propeller design nowadays. On the other side, phase transitions induced by temperature variations can be observed in daily life as boiling, evaporation, and condensation. In industry, liquid-vapor phase transitions take place everyday in steam generators, heat exchangers, and various pipelines. The accompanying thermal effects make the multiphase flow a widely-used mechanism for energy transfer.

To date, many modeling techniques have been designed to simulate multiphase flows. Most of them fall into the category of either the interface-tracking methods or the interface-capturing methods. The interface-tracking methods resolve the interface by aligning the computational mesh along the interface and update the mesh with the fluid flow. This approach gives a sharp and accurate representation of the interface. Despite that, this method requires constantly re-meshing of the computational domain, and it is typically intractable for topological transitions. Three-dimensional problems with severe topological transitions are still notoriously difficult to solve with the interface-tracking methods. The interface-capturing methods use additional unknowns to implicitly represent the interface. The interface is typically immersed in the computational domain. Consequently, the interface representation is less accurate than that of the interface-tracking methods. However, the interface-capturing methods enjoy several advantages: they are relatively easier for implementation, there is no burden for constant mesh updating, and topological transitions are aptly handled. Existing instantiations of the interface-capturing methods include the volume-of-fluid (VOF) method [2] and the level-set method [3]. Both methods have been applied in commercial codes and are still popular in the literature. However, they are not without shortcomings. The VOF method uses a post-processing procedure to construct the interface, which inevitably introduces errors. In the level-set methods, the level-set function needs to be reinitialized every a few steps. The re-initialization procedure is rather ad hoc, and it destroys the conservation structure.
1.2 Phase-field models

To address the aforementioned modeling difficulties, phase-field models were proposed as an alternative interface-capturing method. It uses a so-called phase-field order parameter to distinguish different phases. Phase-field models postulate that the interface has finite width and material properties transit across the interfacial region smoothly but sharply. Based on the postulates, van der Waals developed his Nobel-winning theory to calculate the capillarity for liquid-vapor interfaces. Later, Korteweg developed the so-called Korteweg stress formulation and coupled the van der Waals theory with the hydrodynamic system. Hitherto, the fluid model based on the van der Waals theory is named as the Navier-Stokes-Korteweg equations. This fluid theory is characterized by a non-convex free energy, supplemented with a non-local density gradient term. In mathematics, this non-local term regularizes the singularity introduced by the non-convex free energy function. In physics, the non-local term represents the surface energy. In modern continuum mechanics, this model falls into the category of the grade-N fluid model [?]. In 1985, Dunn and Serrin studied the thermodynamic consistency of the Navier-Stokes-Korteweg equations, and found that for the model to be consistent with the second law, a new term had to be added to the energy equation [?]. They called this non-classical term “interstitial working flux”.

Parallel to the development of the Navier-Stokes-Korteweg equations, another branch of phase-field models have been developed focusing on multicomponent systems. The original idea comes from the work by Cahn and Hilliard [?], in which the authors proposed a fourth order nonlinear diffusion equation to mimic the behavior of a two-component mixture. Recently, the Cahn-Hilliard type models have been generalized to model more complicated multicomponent systems, such as spinodal decomposition [?], tumor growth [?], fingering effect in porous medium [?], etc. A significant progress was made by Gurtin and his collaborators in providing a rational mechanics framework for the Cahn-Hilliard type models [?]. In his theory, a set of forces, called microscopic forces or microforces, were introduced to account for the phase dynamics. Later, this theory was applied to construct plasticity theory of single crystals [?], fracture models [?], alloy models [?], and ferroelectric models [?], to list a few. In Section 2, this theory is adopted as a means to derive constitutive relations for the van der Waals fluid material. Interestingly, the “interstitial working flux” appears naturally in this derivation as the power expenditure of the microstress. This, in part, justifies the work of Dunn and Serrin within the classical rational mechanics framework [?].

Traditional interface-tracking and interface-capturing methods are designed to follow existing interfaces. When dealing with phase transition phenomena, those methods become intractable. One may need to introduce artificial procedures and empirical assumptions [?] to mimic such phenomena. In contrast, the solid mathematical and thermodynamic foundations
of phase-field models allow them to describe these complicated phenomena without resorting to artificial modeling work. In this work, this advantage will be demonstrated by a suite of boiling simulations. Boiling is regarded to be highly difficult for numerical simulations. Traditional models require artificial knowledge, such as the bubble release rate and bubble departure radius, to describe the boiling process. In this work, two and three-dimensional boiling simulations are carried out using the van der Waals fluid model in Section 5.3. Owing to the thermodynamically consistent nature, the dependency on empirical knowledge is significantly reduced, and there is no ad hoc procedure involved. This approach provides unified predictive capability for both nucleate and film boiling.

Despite its success in modeling, phase-field models face several challenges. The entropy function for phase-field models are always non-convex, which creates difficulty for both mathematical analysis and numerical simulation. Phase-field models usually have a high-order differential term, which necessitates novel numerical techniques for discretization. Furthermore, the interface width for real materials is typically a few nanometers. Therefore, adaptive refinement near the interfacial region is demanded for real-world simulations.

1.3 Numerical analysis

In the numerical analysis for nonlinear problems, a central topic is the stability analysis. One significant example is the study of entropy-stable schemes for gas dynamics. It was revealed that the weak form of the compressible Navier-Stokes equations will intrinsically satisfy the Clausius-Duhem inequality by invoking a particular set of variables, namely the entropy variables [?]. In the late 1980s, the space-time formulation was applied to the entropy-variable formulation to construct a fully discrete entropy-stable scheme [?]. Hereafter, the entropy-variable formulation constitutes a foundation for computing compressible flows. Interested readers are referred to [?] for a detailed review. It should be pointed out that the validity of the entropy-variable formulation and the space-time methods are all contingent upon the convexity of the entropy function. For phase-field problems, the non-convexity of the entropy function precludes the possibility of directly applying the aforementioned techniques. In this work, the numerical difficulties are addressed in Section 3. First, the definition of the entropy variables is generalized to the functional setting. Interestingly, it will be revealed in Section 3.3 that the formula for entropy variables is formally invariant under different fluid models. It should be noted that the entropy variables should not be merely regarded as algebraic change-of-variables. In fact, they are mappings from the conservation variables to their dual spaces (see Theorem 3). Invoking the functional entropy variables, we derive an alternative statement of the original Navier-Stokes-Korteweg equations. The weighted residual formula-
tion based on this alternative statement leads to a provably entropy dissipative semi-discrete formulation. Second, to develop a stable temporal scheme, we resort to the method based on a family of new quadrature rules \([?, ?, ?]\). For this thermal problem, the major difficulty comes from the discretization of the energy time derivative, since the isothermal Navier-Stokes-Korteweg equations have been well handled \([?]\). A new jump operator is devised for the total energy. It will be shown that this new jump operator is a third-order perturbation to the classical jump operator. By using the perturbed trapezoidal rules repeatedly, it will be proven that the temporal approximation based on the new jump operator dissipates entropy. Compared with the space-time formulation, the requirement for convexity is released. Hence, it is anticipated that this new temporal discretization technology is applicable to more general problems.

In this work, the Non-Uniform Rational B-Splines (NURBS) are utilized to provide a representation of the geometry as well as an approximation space for the spatial discretization. Invoking the isoparametric philosophy, this approach leads to the NURBS-based isogeometric analysis \([?]\). Isogeometric analysis has been shown to enjoy several desirable numerical properties: (1) it retains an exact representation of the geometry; (2) it possesses a unique \(k\)-refinement technology, which allows one to generate higher-continuity basis functions without proliferation of degrees of freedom; (3) it exhibits superior robustness \([?]\) and accuracy \([?]\) properties compared with traditional finite elements. The above attributes make isogeometric analysis a particularly effective approach in the approximation of phase-field problems \([?]\). As the first instantiation of the isogeometric analysis, the NURBS-based technology has been widely used in both design and analysis \([?]\). Recent advancements of isogeometric analysis include T-splines and isogeometric collocation methods. T-splines allow one to create complicated engineering design in a single watertight geometric model \([?]\) and enable local refinement in analysis \([?]\). Isogeometric collocation methods are shown to be an efficient alternative to isogeometric Galerkin methods \([?]\), which offers a potentially powerful alternative for phase-field simulations \([?]\).

1.4 Structure and content of the paper

The body of this work is organized as follows. In Section 2, a unified modeling framework is derived. The Navier-Stokes-Korteweg equations are recovered within this framework by choosing an appropriate Helmholtz free energy functional. The thermodynamic properties of this model are discussed. In Section 3, provably entropy-stable, second-order time accurate numerical schemes are designed and analyzed for the Navier-Stokes-Korteweg equations. In Section 4, benchmark problems are studied to verify the theoretical estimates. In Section 5,
a suite of application examples, including evaporation, condensation, thermocapillarity, and boiling flows, are numerically investigated using the model and algorithm we developed. We draw conclusions and discuss future research directions in Section 6.

2 The Navier-Stokes-Korteweg equations

2.1 Balance laws

Our discussion of the continuum theory is restricted to the Euclidean space $\mathbb{R}^3$, which is described by a fixed orthonormal vector set $\mathbf{e}_i$, $i = 1, 2, 3$. The continuum body under consideration occupies a region $\mathcal{B} \subset \mathbb{R}^3$, which is referred to as the reference configuration. The material point in $\mathcal{B}$ is labeled by $\mathbf{X} = (X_1, X_2, X_3)^T$. The motion that the continuum body undergoes is denoted as $\mathcal{X} : \mathcal{B} \times [0, \infty) \to \mathbb{R}^3$. The image of $\mathcal{B}$ by $\mathcal{X}$ at time $t$ is denoted as $\mathcal{B}_t$, which is often referred to as the current configuration. The spatial position of material points $\mathbf{X}$ at time $t$ is given by

$$\mathbf{x} = \mathcal{X}(\mathbf{X}, t).$$

$\mathbf{x} = (x_1, x_2, x_3)^T$ is referred to as the spatial coordinates. Here we postulate that the map $\mathcal{X}$ is differentiable, one-to-one, and orientation preserving for each time $t \geq 0$. Consider an arbitrary open set $\Omega$ of $\mathcal{B}$, its image at time $t$ is denoted as $\Omega_t = \mathcal{X}(\Omega, t)$. The boundary $\partial \Omega_t$ is oriented with a unit outward normal vector $\mathbf{n}(\mathbf{x})$. We assume that there exists a density field $\rho(\mathbf{x}, t)$ and a velocity field $\mathbf{u}(\mathbf{x}, t)$ at the current configuration. The spatial velocity field is defined as

$$\mathbf{u}(\mathbf{x}, t) = \frac{\partial}{\partial t} \mathcal{X}(\mathbf{X}, t) = \frac{\partial}{\partial t} \mathcal{X}(\mathbf{X}, t).$$

In the following, we understand $D/Dt$ as the material time derivative, i.e.,

$$\frac{D}{Dt} (\cdot) := \frac{\partial}{\partial t} (\cdot) + \mathbf{u} \cdot \nabla (\cdot).$$

Now, we have the following balance laws that govern the behavior of the continuum body.

- **Conservation of Mass**

$$\frac{d}{dt} \int_{\Omega_t} \rho(\mathbf{x}, t)d\mathbf{V}_x = 0.$$

- **Balance of Linear Momentum**
\[
\frac{d}{dt} \int_{\Omega_t} \rho(x, t)u(x, t)dV_x = \int_{\partial \Omega_t} \sigma(x, t)dA_x + \int_{\Omega_t} \rho b(x, t)dV_x. \tag{2}
\]

Here the traction field is given by \(\sigma(x, t) = T(x, t)n(x)\), where \(T(x, t)\) is the Cauchy stress tensor; \(b(x, t)\) is the external body force per unit mass.

- **Balance of Angular Momentum**

\[
\frac{d}{dt} \int_{\Omega_t} x \times \rho(x, t)u(x, t)dV_x = \int_{\partial \Omega_t} x \times \sigma(x, t)dA_x + \int_{\Omega_t} x \times b(x, t)dV_x. \tag{3}
\]

In our work, the central modeling subject is the liquid-vapor phase transition. The phase-field order parameter for the change of the state of matter is chosen as the density \(\rho\). Following the idea of Gurtin [1], we assume that there exists a set of forces that accounts for the kinematics of phase transitions. These forces are named microforces mainly because they are involved with the local transformation of the material, rather than the macroscopic movements. Here, we assume that the kinematics of \(\rho\) is associated with the following forces:

\(\xi\), the microstress ,

\(\varphi\), the internal microforce,

\(l\), the external microforce.

This set of microforces is balanced as is stated in the following equation.

- **Balance of Microforce Associated with Density Phase Transition**

\[
\int_{\partial \Omega_t} \xi(x, t) \cdot n(x, t)dA_x + \int_{\Omega_t} \varphi dV_x + \int_{\Omega_t} ldV_x = 0. \tag{4}
\]

**Remark 1.** The notion of microforce was initially introduced to generalized the Cahn-Hilliard equation [2]. For a comprehensive review, interested readers are referred to [3].

- **Conservation of Energy**

\[
\frac{d}{dt} \int_{\Omega_t} \rho(x, t)E(x, t)dV_x = \int_{\partial \Omega_t} \left( T(x, t)u(x, t) + \frac{D}{Dt}\rho(x, t)\xi(x, t) - q \right) \cdot ndA_x \\
+ \int_{\Omega_t} b(x, t) \cdot u(x, t) + l(x, t)\frac{D}{Dt}\rho(x, t) + \rho(x, t)r(x, t)dV_x. \tag{5}
\]

Here in equation (5), the following notations are introduced:
\( E(x, t) = \nu(x, t) + \frac{1}{2}|u(x, t)|^2 \), the total energy density per unit mass,
\( \nu(x, t) \), the internal energy density per unit mass,
\( q(x, t) \), the heat flux,
\( r(x, t) \), the heat source per unit mass.

It is noteworthy that besides the traditional working terms of the macroscopic forces and the macroscopic sources, there are non-classical terms contributing to the change of the total energy. These terms are the power expenditures of the microstress \( \xi \) and the external microforce \( l \):

\[
\int_{\partial \Omega_t} \frac{D}{Dt} \rho(x, t) \xi(x, t) \cdot n dA_x, \quad \int_{\Omega_t} l(x, t) \frac{D}{Dt} \rho(x, t) dV_x.
\]

The external microforce does not contribute to the energy change. See [?] for a conceptual explanation.

- **Second Law of Thermodynamics**

\[
\int_{\Omega_t} D(x, t) dV_x \equiv \frac{d}{dt} \int_{\Omega_t} \rho(x, t) s(x, t) dV_x + \int_{\partial \Omega_t} \frac{q(x, t) \cdot n(x)}{\theta(x, t)} dA_x \\
- \int_{\Omega_t} \frac{\rho(x, t) r(x, t)}{\theta(x, t)} dV_x \geq 0. \tag{6}
\]

Here \( D(x, t) \) denotes the total dissipation, \( s(x, t) \) denotes the entropy density, and \( \theta(x, t) \) is the absolute temperature. The above inequality is called the second law of thermodynamics, or the Clausius-Duhem inequality.

Applying the divergence and the Reynolds’ transport theorems, we can obtain the governing equations and the Clausius-Duhem inequality in local forms (omitting the arguments \( x \) and \( t \) for simplicity) as

\[
\frac{D\rho}{Dt} + \rho \nabla \cdot u = 0, \tag{7}
\]
\[
\rho \frac{Du}{Dt} = \nabla \cdot T + \rho b, \tag{8}
\]
\[
T = T^T, \tag{9}
\]
\[
\nabla \cdot \xi + \varphi + l = 0, \tag{10}
\]
\[
\rho \frac{DE}{Dt} = \nabla \cdot \left( Tu + \frac{D\rho}{Dt} \xi - q \right) + \rho b \cdot u + l \frac{D\rho}{Dt} + pr, \tag{11}
\]
\[ D := \rho \frac{D \rho}{D t} + \nabla \cdot \left( \frac{q}{\theta} \right) - \frac{\rho r}{\theta} \geq 0. \] (12)

In addition to the governing equations (7)–(12), there is a balance equation for the internal energy \( \iota \). The total energy balance equation can be expanded first as

\[ \rho \frac{D \iota}{D t} + \rho \mathbf{u} \cdot \frac{D \mathbf{u}}{D t} = \nabla \cdot \mathbf{T} \cdot \mathbf{u} + \mathbf{T} : \nabla \mathbf{u} + \nabla \cdot \xi \frac{D \rho}{D t} + \xi \cdot \nabla \left( \frac{D \rho}{D t} \right) - \nabla \cdot \mathbf{q} + \rho \mathbf{b} \cdot \mathbf{u} + l \frac{D \rho}{D t} + \rho r. \] (13)

The linear momentum balance equations and the microforce balance equation can be utilized to give the following relations.

\[ \rho \mathbf{u} \cdot \frac{D \mathbf{u}}{D t} = \nabla \cdot \mathbf{T} \cdot \mathbf{u} + \rho \mathbf{b} \cdot \mathbf{u}, \] (14)

\[ \nabla \cdot \xi \frac{D \rho}{D t} + l \frac{D \rho}{D t} = -\varphi \frac{D \rho}{D t}. \] (15)

Substituting (14)–(15) into (13), we may obtain a balance equation for the internal energy as follows.

\[ \rho \frac{D \iota}{D t} = \mathbf{T} : \nabla \mathbf{u} - \varphi \frac{D \rho}{D t} + \xi \cdot \nabla \left( \frac{D \rho}{D t} \right) - \nabla \cdot \mathbf{q} + \rho r. \] (16)

This equation will be used as a starting point for the derivation of constitutive relations.

### 2.2 Coleman-Noll type analysis and constitutive relations

To close the model, we still need to provide the constitutive relations for the Cauchy stress, the internal energy density, the entropy density, the heat flux, and the microforces. In this section, we derive the explicit form of the constitutive relations in terms of a thermodynamic potential. In this derivation, the Coleman-Noll type argument is applied so that the resulting constitutive relations will be thermodynamically consistent.

#### 2.2.1 Free energy imbalance

The Helmholtz free energy density per unit mass \( \Psi(x,t) \) is defined by

\[ \Psi(x,t) := \iota(x,t) - \theta(x,t)s(x,t). \]
Taking material time derivatives at both sides, we get the relation

$$\frac{D\psi}{Dt} - \theta \frac{Ds}{Dt} = \frac{D\Psi}{Dt} + s \frac{D\theta}{Dt}. \quad (17)$$

Substituting the internal energy balance equation (16) and the second law of thermodynamics (12) into the above relation, we can get an inequality

$$\rho \frac{D\Psi}{Dt} + \rho s \frac{D\theta}{Dt} \leq T : \nabla u - \varphi \frac{D\rho}{Dt} + \xi \cdot \nabla \left( \frac{D\rho}{Dt} \right) - \frac{q \cdot \nabla \theta}{\theta}. \quad (18)$$

Moving the term $\rho s D\theta / Dt$ to the right hand side, we can get a constraint inequality for $\Psi$ as

$$\rho \frac{D\Psi}{Dt} \leq T : \nabla u - \varphi \frac{D\rho}{Dt} + \xi \cdot \nabla \left( \frac{D\rho}{Dt} \right) - \frac{q \cdot \nabla \theta}{\theta} - \rho s \frac{D\theta}{Dt}. \quad (18)$$

The inequality (18) is referred to as the free energy imbalance. It plays an analogous role to (12) in restricting constitutive relations. In fact, for pure mechanical processes when thermal effects are negligible, the Helmholtz free energy is the thermodynamic potential that characterizes the dissipation behavior of the isothermal system. For an isobaric isothermal process, however, the Gibbs free energy should be chosen as a proper thermodynamic potential [2]. In this work, the isobaric process is not considered. Hence, the Helmholtz free energy is a valid thermodynamic potential. Before proceeding further, we split the Cauchy stress $T$ and the velocity gradient $\nabla u$ into deviatoric and hydrostatic parts.

1. The Cauchy stress $T$ can be split into deviatoric and hydrostatic parts,

$$T = T^d + T^h, \quad (19)$$

where

$$T^d = T - \frac{1}{3} (\text{tr}T) I, \quad (20)$$

$$T^h = \frac{1}{3} (\text{tr}T) I. \quad (21)$$

Here $I$ is the identity tensor, and $\text{tr}(\cdot)$ is the trace operator.

2. The velocity gradient can be split into three parts,

$$\nabla u = L^d + L^h + W, \quad (22)$$
wherein

\[ \mathbf{L}^d = \frac{1}{2} (\nabla \mathbf{u} + \nabla \mathbf{u}^T) - \frac{1}{3} \nabla \cdot \mathbf{u}, \]
\[ \mathbf{L}^h = \frac{1}{3} \nabla \cdot \mathbf{u}, \]
\[ \mathbf{W} = \frac{1}{2} (\nabla \mathbf{u} - \nabla \mathbf{u}^T). \]

In this split, \( \mathbf{L}^d \) and \( \mathbf{L}^h \) are the deviatoric and hydrostatic parts of the rate of strain tensor \( \mathbf{L}; \) \( \mathbf{W} \) is the spin tensor.

Consequently, it is straightforward to make the following observations.

1. According to the mass balance equation (7), we have

\[ \nabla \cdot \mathbf{u} = - \frac{D\rho/ Dt}{\rho}. \]

2. The gradient of material time derivative \( D\rho/ Dt \) can be expanded as

\[ \nabla \left( \frac{D\rho}{Dt} \right) = \frac{D}{Dt} (\nabla \rho) + \nabla \mathbf{u}^T \nabla \rho = \frac{D}{Dt} (\nabla \rho) + \mathbf{L}^d \nabla \rho + \mathbf{W}^T \nabla \rho - \frac{D\rho/ Dt}{3\rho} \nabla \rho. \]

3. Making use of the property of deviatoric tensors, the inner product of \( \mathbf{T} \) and \( \nabla \mathbf{u} \) can be written alternatively as

\[ \mathbf{T} : \nabla \mathbf{u} = \mathbf{T}^d : \mathbf{L}^d + \mathbf{T}^h : \mathbf{L}^h = \mathbf{T}^d : \mathbf{L}^d + \frac{1}{3} (\text{tr} \mathbf{T}) \nabla \cdot \mathbf{u}. \]

Making use of the above observations, the free energy imbalance (18) relation can be rewritten as

\[ \rho \frac{D\psi}{Dt} \leq \mathbf{T}^d : \mathbf{L}^d - \frac{\text{tr} \mathbf{T} D\rho}{3\rho} \frac{D\rho}{Dt} - \varphi \frac{D\rho}{Dt} + \xi \cdot \frac{D}{Dt} (\nabla \rho) + \nabla \rho \cdot \mathbf{L}^d \xi + \nabla \rho \cdot \mathbf{W} \xi - \frac{1}{3\rho} \nabla \rho \cdot \xi \frac{D\rho}{Dt} - \mathbf{q} \cdot \nabla \theta \frac{\theta}{\rho} - \rho_s \frac{D\theta}{Dt}. \]

2.2.2 Coleman-Noll type analysis

Following Truesdell’s principle of equipresence [?], we demand that the constitutive relations are functions depending on \( \rho, \nabla \rho, D\rho/ Dt, \theta, \nabla \theta, \mathbf{L}^d, \) and \( \mathbf{W} \). Specifically, the Helmholtz
free energy density $\Psi$ can be written as

$$\Psi = \Psi \left( \rho, \nabla \rho, \frac{D\rho}{Dt}, \theta, \nabla \theta, L^d, W \right).$$

We take material time derivative of $\Psi$, and the chain rule leads to

$$\frac{D\Psi}{Dt} = \frac{\partial \Psi}{\partial \rho} \frac{D\rho}{Dt} + \frac{\partial \Psi}{\partial (\nabla \rho)} \cdot \frac{D(\nabla \rho)}{Dt} + \frac{\partial \Psi}{\partial (D\rho/ Dt)} \frac{D^2\rho}{Dt^2} + \frac{\partial \Psi}{\partial \theta} \frac{D\theta}{Dt} + \frac{\partial \Psi}{\partial (\nabla \theta)} \cdot \frac{D(\nabla \theta)}{Dt}$$

$$+ \frac{\partial \Psi}{\partial L^d} : \frac{DL^d}{Dt} + \frac{\partial \Psi}{\partial W} : \frac{DW}{Dt}.$$  \hspace{1cm} (30)

Now substituting (30) into the free energy imbalance (29) and making use of the relations (22)-(28), we can get

$$\rho \frac{D\Psi}{Dt} = \rho \left( \frac{\partial \Psi}{\partial \rho} \frac{D\rho}{Dt} + \frac{\partial \Psi}{\partial (\nabla \rho)} \cdot \frac{D(\nabla \rho)}{Dt} + \frac{\partial \Psi}{\partial (D\rho/ Dt)} \frac{D^2\rho}{Dt^2} + \frac{\partial \Psi}{\partial \theta} \frac{D\theta}{Dt} + \frac{\partial \Psi}{\partial (\nabla \theta)} \cdot \frac{D(\nabla \theta)}{Dt}$$

$$+ \frac{\partial \Psi}{\partial L^d} : \frac{DL^d}{Dt} + \frac{\partial \Psi}{\partial W} : \frac{DW}{Dt} \right) \leq \mathbf{T}^d : \mathbf{L}^d - \frac{\text{tr} \mathbf{T} \frac{D\rho}{Dt}}{3\rho} - \varphi \frac{D\rho}{Dt} + \xi \cdot \frac{D(\nabla \rho)}{Dt} + \nabla \rho \cdot \mathbf{L}^d \xi$$

$$+ \nabla \rho \cdot \mathbf{W} \xi - \frac{1}{3\rho} \nabla \rho \cdot \xi \frac{D\rho}{Dt} - \frac{q \cdot \nabla \theta}{\theta} - \rho s \frac{D\theta}{Dt}. \hspace{1cm} (31)$$

Grouping terms together, the above inequality is equivalent to

$$\left( \rho \frac{\partial \Psi}{\partial \rho} + \frac{\text{tr} \mathbf{T}}{3\rho} + \varphi + \frac{1}{3\rho} \nabla \rho \cdot \xi \right) \frac{D\rho}{Dt} + \left( \rho \frac{\partial \Psi}{\partial (\nabla \rho)} - \xi \right) \frac{D(\nabla \rho)}{Dt} + \rho \frac{\partial \Psi}{\partial (D\rho/ Dt)} \frac{D^2\rho}{Dt^2}$$

$$+ \left( \rho \frac{\partial \Psi}{\partial \theta} + \rho s \right) \frac{D\theta}{Dt} + \rho \frac{\partial \Psi}{\partial (\nabla \theta)} \cdot \frac{D(\nabla \theta)}{Dt} + \frac{q \cdot \nabla \theta}{\theta} + \rho \frac{\partial \Psi}{\partial L^d} : \frac{DL^d}{Dt} + \rho \frac{\partial \Psi}{\partial W} : \frac{DW}{Dt}$$

$$- \mathbf{L}^d : (\mathbf{T}^d + \nabla \rho \otimes \xi) - \mathbf{W} : (\nabla \rho \otimes \xi) \leq 0. \hspace{1cm} (32)$$

Through appropriate choice of external forces and external sources, we may have arbitrary levels of the material rates of the state variables in (32) at a particular time. Various constitutive relations may be inferred from the above relation. Here we provide a simple but general set of constitutive relations by invoking the argument made by Coleman and Noll [?]. First, we notice that due to the arbitrariness of $D^2\rho/ Dt^2$,

$$\frac{\partial \Psi}{\partial (D\rho/ Dt)} = 0. \hspace{1cm} (33)$$
Similar arguments results in

\[ \frac{\partial \Psi}{\partial (\nabla \theta)} = 0, \]  
(34)

\[ \frac{\partial \Psi}{\partial L^d} = 0, \]  
(35)

\[ \frac{\partial \Psi}{\partial W} = 0. \]  
(36)

Above relations (33)-(36) imply that the Helmholtz free energy density \( \Psi \) is independent of \( D\rho/Dt, \nabla \theta, L^d \), and \( W \). Hence, it can be written as

\[ \Psi = \Psi (\rho, \nabla \rho, \theta). \]  

The relation (32) is reduced to

\[
\left( \rho \frac{\partial \Psi}{\partial \rho} + \frac{\text{tr} T}{3\rho} + \varphi + \frac{1}{3\rho} \nabla \rho \cdot \xi \right) \frac{D\rho}{Dt} + \left( \rho \frac{\partial \Psi}{\partial (\nabla \rho)} - \xi \right) \cdot \frac{D}{Dt} (\nabla \rho) \\
+ \left( \rho \frac{\partial \Psi}{\partial \theta} + \rho s \right) \frac{D\theta}{Dt} + \frac{q \cdot \nabla \theta}{\theta} - L^d : (T^d + \nabla \rho \otimes \xi) - W : (\nabla \rho \otimes \xi) \leq 0. \]  
(37)

Based on the above inequality, the following choices are made.

\[ \varphi = -\frac{\text{tr} T}{3\rho} - \rho \frac{\partial \Psi}{\partial \rho} - \frac{1}{3\rho} \nabla \rho \cdot \xi - \mathfrak{B} \frac{D\rho}{Dt}, \]  
(38)

\[ \xi = \rho \frac{\partial (\nabla \rho)}{\partial \rho}, \]  
(39)

\[ s = -\frac{\partial \Psi}{\partial \theta}, \]  
(40)

\[ q = -\kappa \nabla \theta, \]  
(41)

\[ T^d = D\mathbb{L}^d - \frac{1}{3} \text{tr}(D\mathbb{L}^d) I - \frac{1}{2} (\nabla \rho \otimes \xi + \xi \otimes \nabla \rho) + \frac{1}{3} \nabla \rho \cdot \xi I. \]  
(42)

These choices will be shown to be sufficient to guarantee the inequality in the next section. In the meantime, we demand that the constitutive relation for \( \xi \) should respect

\[ \nabla \rho \otimes \xi = \xi \otimes \nabla \rho. \]  
(43)
This relation may result from the frame indifference. In conjunction with (39), it can be rewritten as

\[ \nabla \rho \otimes \rho \frac{\partial \Psi}{\partial (\nabla \rho)} = \rho \frac{\partial \Psi}{\partial (\nabla \rho)} \otimes \nabla \rho. \tag{44} \]

It poses a constraint on how should the non-local gradient term \( \nabla \rho \) enter into the free energy density function \( \Psi \). It has been revealed in \([?]\) that terms in the form of \( \mathbf{d} \cdot \nabla \rho \) or \( \mathbf{C} : \nabla^2 \rho \), with \( \mathbf{d} \) being a constant vector and \( \mathbf{C} \) being a constant second-order tensor, cannot enter into the free energy density function \( \Psi \). This assertion can be easily justified using the constraint relation (44). We will only consider the case with \( \nabla \rho \) entered into the free energy density function \( \Psi \) as \( |\nabla \rho|^2 \). This is in fact the case considered by van der Waals in his seminal work \([?]\). This special choice for the Helmholtz free energy density function guarantees the satisfaction of the relation (43).

In (38), \( \mathfrak{B} \) is a scalar; \( \kappa \) is a second-order tensor in (41); \( \mathbb{D} \) is a fourth-order tensor in (42). The choices (38)-(42) and the constraint relation (43) are sufficient but not necessary to guarantee the inequality (37). Other choices conforming to (37) can be made to generate more sophisticated models. Our choices should not be regarded as the unique solutions to the inequality (37). But we will show that the choices made here are general enough to recover a number of meaningful models.

### 2.2.3 Constitutive relations

Based on the relations (38)-(42), we can obtain the constitutive relations expressed in terms of \( \Psi \).

#### Microstress

The relation (39) gives the constitutive relation for the microstress straightforwardly.

\[ \xi = \rho \frac{\partial \Psi}{\partial (\nabla \rho)}. \tag{45} \]

#### Cauchy stress

From the relations (38), (39), (41), and the microforce balance equation (10), we have the constitutive relation for \( \text{tr}\mathbf{T} \) as

\[ \frac{\text{tr}\mathbf{T}}{3} = \rho \nabla \cdot \left( \rho \frac{\partial \Psi}{\partial (\nabla \rho)} \right) - \rho^2 \frac{\partial \Psi}{\partial \rho} - \frac{1}{3} \rho \frac{\partial \Psi}{\partial (\nabla \rho)} \cdot \nabla \rho + \rho l - \mathfrak{B} \rho \frac{D \rho}{Dt}. \tag{46} \]

Replacing the microstress \( \xi \) by the relations (39), the deviatoric part of the Cauchy
stress is given by the choice (42).

\[ T^d = \mathbb{D} L^d - \frac{1}{3} \text{tr}(\mathbb{D} L^d) \mathbf{I} - \frac{\rho}{2} \left( \nabla \rho \otimes \frac{\partial \Psi}{\partial (\nabla \rho)} + \frac{\partial \Psi}{\partial (\nabla \rho)} \otimes \nabla \rho \right) + \frac{\rho}{3} \nabla \rho : \frac{\partial \Psi}{\partial (\nabla \rho)} \mathbf{I}. \] (47)

Combining the two parts, the Cauchy stress \( \mathbf{T} \) reads

\[ \mathbf{T} = T^d + \frac{\text{tr} \mathbf{T}}{3} \mathbf{I} \]

\[ = \mathbb{D} L^d - \frac{1}{3} \text{tr}(\mathbb{D} L^d) \mathbf{I} - \frac{\rho}{2} \left( \nabla \rho \otimes \frac{\partial \Psi}{\partial (\nabla \rho)} + \frac{\partial \Psi}{\partial (\nabla \rho)} \otimes \nabla \rho \right) \]

\[ + \left( \rho \nabla \cdot \left( \frac{\rho \partial \Psi}{\partial (\nabla \rho)} \right) - \rho^2 \frac{\partial \Psi}{\partial \rho} + \rho l - \Omega \frac{D \rho}{Dt} \right) \mathbf{I}. \] (48)

**Heat flux**

The constitutive relation for the heat flux is given by the choice (41), i.e.,

\[ \mathbf{q} = -\kappa \nabla \theta. \] (49)

This choice agrees with the Fourier’s law [?].

**Entropy**

The relation (40) defines the entropy density \( s \) as

\[ s = -\frac{\partial \Psi}{\partial \theta}. \] (50)

This definition coincides with the classical thermodynamic definition [?]. Consequently, the internal energy density \( \iota \) is given by

\[ \iota = \Psi + \theta s = \Psi - \theta \frac{\partial \Psi}{\partial \theta}. \] (51)

### 2.3 Dissipation inequalities

In this section, the choices (38)-(42) are validated by analyzing the dissipation of the model. It will be clear how different terms enter into the dissipative mechanisms in isolated and isothermal processes.

**Lemma 1.** Given the constitutive relations (45)–(51), the dissipation \( \mathcal{D} \) defined in (12) takes
the form
\[ D = \frac{1}{\theta} \mathbf{L}^d : \mathbf{D} \mathbf{L}^d + \frac{1}{\theta} B \left( \frac{D \rho}{D t} \right)^2 + \frac{1}{\theta^2} \nabla \theta \cdot \kappa \nabla \theta. \] (52)

**Proof.** We start by considering the internal energy balance equation
\[ \rho \frac{D t}{D t} = \mathbf{T} : \nabla \mathbf{u} - \varphi \frac{D \rho}{D t} + \xi \cdot \nabla \left( \frac{D \rho}{D t} \right) - \nabla \cdot \mathbf{q} + \rho r. \] (53)

It is known from (28) that
\[ \mathbf{T} : \nabla \mathbf{u} = \mathbf{T}^d : \mathbf{L}^d + \frac{1}{3} (\text{tr} \mathbf{T}) \nabla \cdot \mathbf{u}. \] (54)

Making use of the constitutive relation (47), we have
\[ \mathbf{T}^d : \mathbf{L}^d = \mathbf{D} \mathbf{L}^d - \frac{1}{3} \text{tr}(\mathbb{D} \mathbf{L}^d) \mathbf{I} : \mathbf{L}^d - \frac{\rho}{2} \left( \nabla \rho \otimes \frac{\partial \Psi}{\partial (\nabla \rho)} + \frac{\partial \Psi}{\partial (\nabla \rho)} \otimes \nabla \rho \right) : \mathbf{L}^d \]
\[ + \frac{\rho}{3} \nabla \rho \cdot \frac{\partial \Psi}{\partial (\nabla \rho)} \mathbf{I} : \mathbf{L}^d \]
\[ = \mathbf{D} \mathbf{L}^d - \frac{\rho}{2} \left( \nabla \rho \otimes \frac{\partial \Psi}{\partial (\nabla \rho)} + \frac{\partial \Psi}{\partial (\nabla \rho)} \otimes \nabla \rho \right) : \mathbf{L}^d, \] (55)

since \( \mathbf{I} : \mathbf{L}^d = \text{tr} \mathbf{L}^d = 0 \). According to the constitutive relation (46), we have
\[ \frac{1}{3} (\text{tr} \mathbf{T}) \nabla \cdot \mathbf{u} = \rho \nabla \cdot \left( \rho \frac{\partial \Psi}{\partial (\nabla \rho)} \right) \nabla \cdot \mathbf{u} - \rho \frac{\partial \Psi}{\partial \rho} \nabla \cdot \mathbf{u} - \frac{1}{3} \rho \frac{\partial \Psi}{\partial (\nabla \rho)} \cdot \nabla \rho \nabla \cdot \mathbf{u} \]
\[ + \rho \left( \frac{\partial \Psi}{\partial (\nabla \rho)} \right) \frac{D \rho}{D t} \nabla \cdot \mathbf{u} \]
\[ = - \nabla \cdot \left( \rho \frac{\partial \Psi}{\partial (\nabla \rho)} \right) \frac{D \rho}{D t} + \frac{\partial \Psi}{\partial \rho} \frac{D \rho}{D t} + \frac{1}{3} \frac{\partial \Psi}{\partial (\nabla \rho)} \cdot \nabla \rho \frac{D \rho}{D t} \]
\[ - \mathbf{I} \frac{D \rho}{D t} + \mathbf{B} \rho^2 (\nabla \cdot \mathbf{u})^2. \] (56)

Recalling from the relation (27), we have
\[ \xi : \nabla \left( \frac{D \rho}{D t} \right) = \xi : \left[ \frac{D}{D t} (\nabla \rho) + \mathbf{L}^d \nabla \rho + \mathbf{W}^T \nabla \rho - \frac{D \rho / D t}{3 \rho} \nabla \rho \right] \]
\[ = \rho \frac{\partial \Psi}{\partial (\nabla \rho)} \cdot \left[ \frac{D}{D t} (\nabla \rho) + \mathbf{L}^d \nabla \rho + \mathbf{W}^T \nabla \rho - \frac{D \rho / D t}{3 \rho} \nabla \rho \right]. \] (57)
The microforce balance equation implies \( \varphi = -\nabla : \xi - l \). Consequently, we have

\[
\varphi \frac{D\rho}{Dt} = -\nabla \cdot \xi \frac{D\rho}{Dt} - l \frac{D\rho}{dD}.
\] (58)

Now substituting (54)-(58) into (53), and using (43) repeatedly, we obtain

\[
\rho \frac{D^2}{Dt} = \mathbb{L}^d : \mathbb{L}^d \rho - \rho \left( \frac{1}{2} \left( \nabla \frac{D\Psi}{D\rho} + \frac{\partial \Psi}{\partial \nabla \rho} \otimes \nabla \rho \right) \right) : \mathbb{L}^d - \nabla \cdot \left( \rho \frac{\partial \Psi}{\partial \nabla \rho} \right) \frac{D\rho}{Dt} + l \frac{D\rho}{dD} + \mathbb{B} \rho \rho^2 (\nabla \cdot \mathbf{u})^2 + \nabla \cdot \xi \frac{D\rho}{Dt} + l \frac{D\rho}{dD}.
\]

Moving all time derivative terms to the left hand side yields

\[
\rho \frac{D^2}{Dt} = \frac{1}{\theta} \mathbb{L}^d : \mathbb{L}^d \rho + \frac{1}{\theta} \mathbb{B} \rho^2 (\nabla \cdot \mathbf{u})^2 - \frac{1}{\theta} \nabla \cdot \mathbf{q} + \frac{1}{\theta} \rho r.
\]

By definition, we have

\[
\mathcal{D} := \rho \frac{D^2}{Dt} + \nabla \cdot \left( \frac{\mathbf{q}}{\theta} \right) - \rho \frac{r}{\theta} = \frac{1}{\theta} \mathbb{L}^d : \mathbb{L}^d \rho + \frac{1}{\theta} \mathbb{B} \rho^2 (\nabla \cdot \mathbf{u})^2 - \frac{\mathbf{q} \cdot \nabla \theta}{\theta^2} = \frac{1}{\theta} \mathbb{L}^d : \mathbb{L}^d \rho + \frac{1}{\theta} \mathbb{B} \rho^2 (\nabla \cdot \mathbf{u})^2 + \frac{\nabla \theta \cdot \kappa \nabla \theta}{\theta^2},
\]

which completes the proof.

The dissipation formulation (52) suggests that the model will guarantee the second law of thermodynamics if the material moduli are positive semi-definite, which is summarized in the following theorem.

**Theorem 1.** If \( \mathbb{D} \) is a positive semi-definite fourth-order tensor, \( \kappa \) is a positive semi-definite second-order tensor, and \( \mathbb{B} \geq 0 \), the system of balance equations (7)-(11) satisfies the second
law of thermodynamics in the following sense.

\[
\mathcal{D} = \frac{1}{\theta} \mathbf{L}^d \cdot \mathbf{D} \mathbf{L}^d + \frac{1}{\theta} \mathbf{B} \rho^2 (\nabla \cdot \mathbf{u})^2 + \frac{\nabla \theta \cdot \kappa \nabla \theta}{\theta^2} \geq 0.
\]

The proof of this theorem follows straightforwardly from Lemma 1. The significance of this theorem is that the modeler only needs to design an explicit formulation for the thermodynamic potential. Once it is given, the model is closed with non-negative dissipation. Under isothermal condition, the entropy dissipation relation will degenerate into an inequality for the summation of the Helmholtz free energy and the kinetic energy.

Lemma 2. Under the isothermal condition, if \( \mathbf{u} = 0 \) and \( \xi \cdot \mathbf{n} = 0 \) on the boundary \( \partial \Omega_t \), the following relation holds.

\[
\frac{d}{dt} \int_{\Omega_t} \rho \left( \Psi + \frac{1}{2} |\mathbf{u}|^2 \right) dV = \int_{\Omega_t} \left( \rho \mathbf{b} \cdot \mathbf{u} + l \frac{D\rho}{Dt} - \theta \mathcal{D} \right) dV.
\]  

(59)

Proof. Since \( \theta \) is constant, according to \( \Psi = \iota - \theta s \), one has

\[
\frac{D\Psi}{Dt} = \frac{D\iota}{Dt} - \theta \frac{Ds}{Dt}.
\]

and

\[
\Psi + \frac{1}{2} |\mathbf{u}|^2 = \iota + \frac{1}{2} |\mathbf{u}|^2 - \theta s.
\]

Multiplying the above equation with \( \rho \) and integrating over \( \Omega_t \) results in

\[
\frac{d}{dt} \int_{\Omega_t} \rho \left( \Psi + \frac{1}{2} |\mathbf{u}|^2 \right) dV = \frac{d}{dt} \int_{\Omega_t} \rho \left( \iota + \frac{1}{2} |\mathbf{u}|^2 - \theta s \right) dV
\]

\[
= \int_{\partial \Omega_t} \left( \mathbf{T} \mathbf{u} + \frac{D\rho}{Dt} \xi \right) \cdot \mathbf{n} dA + \int_{\Omega_t} \left( \rho \mathbf{b} \cdot \mathbf{u} + l \frac{D\rho}{Dt} - \theta \mathcal{D} \right) dV.
\]

The boundary integral terms are canceled due to the boundary conditions, and hence

\[
\frac{d}{dt} \int_{\Omega_t} \rho \left( \Psi + \frac{1}{2} |\mathbf{u}|^2 \right) dV = \int_{\Omega_t} \left( \rho \mathbf{b} \cdot \mathbf{u} + l \frac{D\rho}{Dt} - \theta \mathcal{D} \right) dV,
\]

which completes the proof of the lemma. \[\square\]

Based on Lemma 2, we may obtain the following stability theorem for isothermal processes.
Figure 1: Illustration of the contact angle boundary condition (60). The red arrow points in the direction $-\nabla \rho/\|\nabla \rho\|$.

**Theorem 2.** If (1) the system undergoes an isothermal process, (2) $\mathbf{u} = 0$ and $\xi \cdot \mathbf{n} = 0$ on the boundary $\partial \Omega$, (3) the forces $\mathbf{b} = 0$ and $l = 0$ in $\Omega$, and (4) the material moduli $\mathbb{D}$ and $\mathbb{B}$ are positive semi-definite, the stability of the system is given by the following dissipation relation.

$$
\frac{d}{dt} \int_{\Omega} \rho \left( \Psi + \frac{1}{2} |\mathbf{u}|^2 \right) dV_x = - \int_{\Omega} \left( \mathbf{L}^d : \mathbb{D} \mathbf{L}^d + \mathbb{B} \rho^2 (\nabla \cdot \mathbf{u})^2 \right) dV_x \leq 0.
$$

**Remark 2.** According to the constitutive relation (45), the boundary condition $\xi \cdot \mathbf{n} = 0$ is equivalent to $\nabla \rho \cdot \mathbf{n} = 0$. The general contact-angle boundary condition is

$$
- \frac{\nabla \rho}{\|\nabla \rho\|} = \cos(\phi),
$$

wherein

$$
\|\nabla \rho\| = \sqrt{\nabla \rho \cdot \nabla \rho},
$$

and $\phi$ is the contact angle of the diffuse-interface against the wall boundary measured in the vapor phase (see Figure 1). Hence, $\nabla \rho \cdot \mathbf{n} = 0$ gives the ninety-degree contact angle boundary condition.
2.4 The van der Waals fluid model

In the preceding section, a general continuum mechanics modeling framework has been established, with the objective of taking non-local effects into account. Theorems 1 and 2 reveal that the model is thermodynamically consistent if the material moduli are positive semi-definite. Thus, the modeling work is principally reduced to a proper design of the thermodynamic potential. This design procedure is primarily based on the consideration of thermodynamics. Our discussion will focus on the van der Waals fluid. The full thermomechanical theory of the van der Waals fluid, initially derived by Dunn and Serrin [495], will be recovered. We will discuss preliminary thermodynamic properties of the system.

2.4.1 Governing equations

Van der Waals’ Nobel-winning theory [269] is considered well-suited for describing liquid-vapor phase transitions. In thermodynamics, the Helmholtz free energy density for the van der Waals fluid, \( \Psi \), is given by

\[
\Psi(\rho, \theta, \nabla \rho) = \Psi_{loc}(\rho, \theta) + \frac{\lambda}{2\rho} |\nabla \rho|^2, \tag{61}
\]

\[
\Psi_{loc}(\rho, \theta) = -a\rho + R\theta \log\left(\frac{\rho}{b - \rho}\right) - C_v \theta \log\left(\frac{\theta}{\theta_{ref}}\right) + C_v \theta, \tag{62}
\]

where \( a, b \) are associated with fluid properties whose meanings will be revealed in the coming discussion; \( \theta_{ref} > 0 \) is the reference temperature value for the model; \( R \) is the specific gas constant; \( C_v \) is the specific heat capacity for the van der Waals fluid; \( \lambda \) is the capillary coefficient. In this work, we assume \( \lambda \) is a constant. With the Helmholtz free energy given, the constitutive relations can be readily obtained. According to (45), the microstress for the van der Waals fluid is

\[
\xi = \rho \frac{\partial \Psi}{\partial (\nabla \rho)} = \lambda \nabla \rho.
\]

Following (48), the Cauchy stress can be written explicitly as

\[
T = \mathbb{D}L - \frac{1}{3} \text{tr}(\mathbb{D}L) I - \rho \left(\nabla \rho \otimes \frac{\partial \Psi}{\partial (\nabla \rho)} + \frac{\partial \Psi}{\partial (\nabla \rho)} \otimes \nabla \rho\right)
+ \left(\rho \nabla \cdot \left(\rho \frac{\partial \Psi}{\partial (\nabla \rho)}\right) - \rho^2 \frac{\partial \Psi}{\partial \rho} + \rho l + \mathfrak{B} \rho^2 \nabla \cdot \mathbf{u}\right) I
= \mathbb{D}L - \frac{1}{3} \text{tr}(\mathbb{D}L) I - \lambda \nabla \rho \otimes \nabla \rho + \left(\lambda \rho \Delta \rho - \rho^2 \frac{\partial \Psi}{\partial \rho} + \rho l + \mathfrak{B} \rho^2 \nabla \cdot \mathbf{u}\right) I.
\]
For convenience, the Cauchy stress can be split into three parts:

\[
\mathbf{T} = \mathbf{\tau} + \mathbf{\varsigma} - p\mathbf{I},
\]  

(63)

wherein

\[
\mathbf{\tau} = \mathbb{D} \mathbf{L}^d - \frac{1}{3} \text{tr} (\mathbb{D} \mathbf{L}^d) \mathbf{I} + \mathfrak{B} \rho^2 \nabla \cdot \mathbf{u} \mathbf{I},
\]  

(64)

\[
\mathbf{\varsigma} = -\lambda \rho \nabla \rho \otimes \nabla \rho + \left(\lambda \rho \Delta \rho + \frac{\lambda}{2} |\nabla \rho|^2 + \rho \mathfrak{L}\right) \mathbf{I},
\]  

(65)

\[
p = \rho^2 \frac{\partial \Psi_{loc}}{\partial \rho} = Rb \frac{\rho \theta}{b - \rho} - a \rho^2.
\]  

(66)

Here, \(\mathbf{\tau}\) represents the viscous shear stress, \(\mathbf{\varsigma}\) represents the capillarity, and \(p\) stands for the thermodynamic pressure. In the subsequent discussion, we assume

\[l = 0,\]
\[\mathbb{D}_{ijkl} = 2\mu \delta_{ik} \delta_{jl},\]
\[\mathfrak{B} = \left(\tilde{\lambda} + \frac{2}{3} \tilde{\mu}\right) \frac{1}{\rho^2},\]

in which \(\tilde{\mu}\) and \(\tilde{\lambda}\) are the first and second viscosity coefficients. Under these choices,

\[
\mathbf{\varsigma} = -\lambda \rho \nabla \rho \otimes \nabla \rho + \left(\lambda \rho \Delta \rho + \frac{\lambda}{2} |\nabla \rho|^2 \right) \mathbf{I}
\]

is identical to the stress derived by and named after Korteweg [?];

\[
\mathbf{\tau} = \tilde{\mu} \left(\nabla \mathbf{u} + (\nabla \mathbf{u})^T\right) + \tilde{\lambda} \nabla \cdot \mathbf{u} \mathbf{I}
\]

is the shear stress for Newtonian fluids. The heat flux \(\mathbf{q}\), the entropy density \(s\), and the internal energy density \(\iota\) are

\[
\mathbf{q} = -\kappa \nabla \theta,
\]
\[
s = -R \log \left(\frac{\rho}{b - \rho}\right) + C_v \log \left(\frac{\theta}{\theta_{ref}}\right),
\]
\[
\iota = -a \rho + C_v \theta + \frac{\lambda}{2\rho} |\nabla \rho|^2.
\]
It should be noticed that based on the choice of the material modulus $D$, the Cauchy stress $T$ satisfies

$$T = T^T,$$

which implies that the angular momentum balance equation (9) is already satisfied. We recall that in the derivation of the constitutive relation for $\text{tr}T$ in (46), the microforce balance equation is used. Similarly to the angular momentum balance equation, the microforce balance equation (10) is satisfied by the constitutive relations and decoupled from the system.

Let us denote the power expenditure of the microstress as $\Pi = \xi D\rho/Dt = \lambda \rho \nabla \cdot u \nabla \rho$. The governing equation for the van der Waals fluid in terms of the conservation variables are

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho u) = 0, \quad (67)$$

$$\frac{\partial (\rho u)}{\partial t} + \nabla \cdot (\rho u \otimes u) + \nabla p - \nabla \cdot \tau - \nabla \cdot \varsigma = \rho b, \quad (68)$$

$$\frac{\partial (\rho E)}{\partial t} + \nabla \cdot ((\rho E + p) u - (\tau + \varsigma) u) + \nabla \cdot q + \nabla \cdot \Pi = \rho b \cdot u + \rho r. \quad (69)$$

This system of equations is commonly known as the Navier-Stokes-Korteweg equations [?]. According to Lemma 1, the dissipation for the system is

$$\mathcal{D} = \frac{1}{\theta} L^d : D L^d + \frac{1}{\theta} \mathfrak{B} \rho^2 (\nabla \cdot u)^2 + \frac{1}{\theta^2} \nabla \theta \cdot \kappa \nabla \theta$$

$$= \frac{2\mu}{\theta} L^d : L^d + \frac{1}{\theta} \left( \tilde{\lambda} + \frac{2}{3} \tilde{\mu} \right) (\nabla \cdot u)^2 + \frac{1}{\theta^2} \nabla \theta \cdot \kappa \nabla \theta. \quad (70)$$

To ensure the second law of thermodynamics, it is sufficient to require that

$$\tilde{\mu} \geq 0, \quad \tilde{\lambda} + \frac{2}{3} \tilde{\mu} \geq 0, \quad \kappa \text{ is positive semi-definite.}$$

In contrast to the compressible Navier-Stokes equations, the term $\Pi$ is an unfamiliar term appearing in the energy equation (69). This term was initially introduced by Dunn and Serrin to enforce the thermodynamic consistency and was named as the “interstitial working flux” [?]. In our framework, $\nabla \cdot \Pi$ appears naturally as the power expenditure of the microstress $\xi$. The previously mysterious term finds a rational mechanics explanation in the microforce theory [?].

**Remark 3.** If we assume that the interface parameter $\lambda$ is constant, the capillary force term
Figure 2: Illustration of the van der Waals pressure $p$ given by (66) at different temperatures. The colored squares delimit the elliptic regions. The critical point is marked by a black circle.

$\nabla \cdot \varsigma$ can be written in the following non-conservative form.

$$\nabla \cdot \varsigma = \lambda \rho \nabla (\Delta \rho).$$

(71)

**Remark 4.** Choosing the Helmholtz free energy density function as

$$\Psi = R \theta \log (\rho) - C_v \theta \log \left( \frac{\theta}{\theta_{ref}} \right) + C_v \theta,$$

the compressible Navier-Stokes equations can be recovered.

### 2.4.2 Thermodynamic properties

We start the discussion on the thermodynamic properties by defining the critical point. The critical point $(\rho_{crit}, \theta_{crit})$ is defined to be the values of density and temperature that satisfy

$$\frac{\partial p}{\partial \rho}(\rho_{crit}, \theta_{crit}) = 0, \quad \frac{\partial^2 p}{\partial \rho^2}(\rho_{crit}, \theta_{crit}) = 0.$$
Figure 3: Comparison of the van der Waals equation of state with real fluids at temperature $\theta = 0.85\theta_{\text{crit}}$. The data of water, carbon dioxide, methane, and propane are obtained from [?] and scaled to dimensionless form. Figure (b) gives a detailed view in the vapor phase.
Simple calculations show that the solutions of the above equations are

\[ \rho_{\text{crit}} = \frac{b}{3}, \quad \theta_{\text{crit}} = \frac{8ab}{27R}, \]

and the critical pressure is \( p_{\text{crit}} := p(\rho_{\text{crit}}, \theta_{\text{crit}}) = ab^2/27 \). In Figure 2, the van der Waals pressure function is plotted as a function of density by fixing the temperature. It can be observed from the figure that the pressure function is not monotone when the temperature is below the critical temperature, and there is a region in which the pressure drops with the increase of the density. This region is commonly referred to as the elliptic region, since the system of conservation equations is of the first-order elliptic type in the vanishing viscosity-capillarity limit within this region. The approximation property of the van der Waals equation of state is demonstrated by comparing with the data for real fluids. In Figure 3, the van der Waals equation of state is plotted as a blue solid curve as a function of density at temperature \( \theta = 0.85\theta_{\text{crit}} \). The thermodynamic data for water, carbon dioxide, methane, and propane are downloaded from the NIST database \([?]\) and plotted in the same figure in dimensionless quantities. As can be seen, the van der Waals model gives qualitatively accurate description of various fluids in both vapor and liquid states. Considering a binomial expansion

\[
\left(1 - \frac{\rho}{b}\right)^{-1} \approx 1 + \frac{\rho}{b} + \frac{\rho^2}{b^2}, \quad \text{when } |\frac{\rho}{b}| \ll 1,
\]

the thermodynamic pressure can be approximated as

\[
p \approx R\theta \rho \left(1 + \left(\frac{1}{b} - \frac{a}{R\theta}\right) \rho^2 + \frac{1}{b^2} \rho^3\right),
\]

when the density is small. This suggests that the van der Waals theory can be viewed as a high-order modification of the perfect gas law. Nowadays, modifications of the van der Waals model are introduced by adding more high-order terms to tune the approximation property for specific materials. Examples include the Beattie-Bridgeman equation \([?]\) and the Benedict-Webb-Rubin equation \([?]\). Another modification was made by Serrin \([?]\), who introduced a new equation of state in the form

\[
p^{\text{serrin}} = Rb \frac{\rho\theta}{b - \rho} - a\hat{s} \hat{r} \rho^\hat{s},
\]

wherein \( \hat{s} < 1 \) and \( \hat{r} > 1 \) are two parameters. This model was claimed to give very accurate pressure curve over a large range of temperature.
Next, let us introduce the local electrochemical potential $\nu_{\text{loc}}$ as

$$\nu_{\text{loc}} := \frac{\partial (\rho \Psi_{\text{loc}})}{\partial \rho}. $$

It does not come from our preceding thermomechanical theory. It is a pure thermodynamic quantity. With the local Helmholtz free energy function given in (62), the electrochemical potential can be written explicitly as

$$\nu_{\text{loc}} = -2a\rho + R\theta \log \left( \frac{\rho}{b - \rho} \right) + \frac{R\theta b}{b - \rho} - C_v \theta \log \left( \frac{\theta}{\theta_{\text{ref}}} \right) + C_v \theta. $$

The equilibrium state at a given temperature can be determined by constructing a common tangent line passing thorough the free energy curve $\rho \Psi_{\text{loc}}$ at two points $\left( \rho_l, \rho_l \Psi_{\text{loc}}(\rho_l) \right)$ and $\left( \rho_v, \rho_v \Psi_{\text{loc}}(\rho_v) \right)$. These two points correspond to the energetically stable liquid and vapor states at the temperature and are usually referred to as the Maxwell states. Mathematically,
Figure 5: Illustration of the elliptic region, the metastable regions, the spinodal line, and the binodal line for the van der Waals fluid.

The common tangent line requires that

\[
\frac{\partial (\rho \Psi_{\text{loc}})}{\partial \rho}(\rho_v) = \frac{\partial (\rho \Psi_{\text{loc}})}{\partial \rho}(\rho_l),
\]

(73)

\[
\rho_v \frac{\partial (\rho \Psi_{\text{loc}})}{\partial \rho}(\rho_v) - \rho_v \Psi_{\text{loc}}(\rho_v) = \rho_l \frac{\partial (\rho \Psi_{\text{loc}})}{\partial \rho}(\rho_l) - \rho_l \Psi_{\text{loc}}(\rho_l).
\]

(74)

The relation (73) implies the local electrochemical potentials \( \nu_{\text{loc}} \) at the two states are identical. The relation (74) can be rewritten as

\[
\rho_v^2 \frac{\partial \Psi_{\text{loc}}}{\partial \rho}(\rho_v) = \rho_l^2 \frac{\partial \Psi_{\text{loc}}}{\partial \rho}(\rho_l),
\]

or, equivalently, \( p(\rho_v) = p(\rho_l) \). Therefore, the system is in electrochemical and mechanical equilibrium at the Maxwell states. The Maxwell states together with the common tangent line are illustrated in Figure 4. It can be clearly observed from the figure that the common tangent line lies below the energy curve, which implies the two-phase state is favored against the homogeneous mixture state, according to the minimum energy principle.

The thermodynamic properties of the van der Waals fluid model can be better understood by drawing a \( \theta-\rho \) phase diagram. In Figure 5, the elliptic region is circumscribed by the
dashed spinodal line and is colored in grey. By connecting the Maxwell states, we get the binodal line, which is drawn as the black solid curve in Figure 5. The regions enclosed by the binodal line and the spinodal line are the liquid and vapor metastable regions, which are colored in green and blue respectively. The metastable states are physically accessible but energetically unstable. With enough thermodynamic perturbations, the energy barrier may be overcome and the metastable states may evolve toward a more stable two-phase system. The binodal line and the spinodal line meet at the critical point. Above the critical temperature, the fluid becomes supercritical, and there is no more distinct liquid-vapor states.

3 Numerical analysis

In this section, we focus on the design of numerical schemes for the Navier-Stokes-Korteweg equations that preserve critical structure of the original strong problem.

3.1 Initial-boundary value problem for the Navier-Stokes-Korteweg equations

We consider a fixed, open, connected, and bounded domain $\Omega \subset \mathbb{R}^d$, where $d$ is the number of spatial dimensions. The boundary of $\Omega$ is denoted as $\partial \Omega$ and is assumed to be sufficiently smooth. The time interval of interest is denoted $(0, T)$, with $T > 0$. The Navier-Stokes-Korteweg equations are considered in the space-time domain $\Omega \times (0, T)$ as

\[
\begin{align*}
\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho u) &= 0, \\
\frac{\partial (\rho u)}{\partial t} + \nabla \cdot (\rho u \otimes u + pI) - \nabla \cdot \tau - \nabla \cdot \zeta &= \rho b, \\
\frac{\partial (\rho E)}{\partial t} + \nabla \cdot (\rho E + p) u - (\tau + \zeta) u + \nabla \cdot q + \nabla \cdot \Pi &= \rho b \cdot u + \rho r.
\end{align*}
\]

In this section, we impose periodic boundary conditions for all variables. Therefore, the problem can be regarded to be a periodic flow posed on a $d$-dimensional torus $\mathbb{T}^d$ in space. Given $\rho_0 : \Omega \to (0, b)$, $u_0 : \Omega \to \mathbb{R}^d$, and $\theta_0 : \Omega \to \mathbb{R}$ as the initial density, velocity, and temperature, the initial conditions for the strong problem (75)-(77) can be stated as

\[
\begin{align*}
\rho(x, 0) &= \rho_0(x), \\
u(x, 0) &= u_0(x), \\
\theta(x, 0) &= \theta_0(x),
\end{align*}
\]
for \( x \in \Omega \). In the above balance equations, \( \tau \) is the viscous shear stress; \( \varsigma \) is the Korteweg stress; \( p \) is the thermodynamic pressure; \( q \) is the heat flux; \( \Pi \) is the interstitial working flux or the power expenditure of the microstress; \( b : \Omega \times (0, T) \to \mathbb{R}^d \) is the prescribed body force per unit mass. The constitutive relations for these quantities have been given in Section 2.2.3. For the completeness of this section, we list them here:

\[
\tau = \mu (\nabla u + \nabla u^T) + \lambda \nabla \cdot uI,
\]

\[
\varsigma = \left( \lambda \rho \Delta \rho + \frac{\lambda}{2} |\nabla \rho|^2 \right) I - \lambda \nabla \rho \otimes \nabla \rho,
\]

\[
p = R b \theta \rho - \rho - a \rho^2,
\]

\[
q = -\kappa \nabla \theta,
\]

\[
\Pi = \lambda \rho \nabla \cdot u \nabla \rho.
\]

**Remark 5.** In the remainder of this work, the Stokes’ hypothesis is adopted, i.e.,

\[
\bar{\lambda} = -\frac{2}{3} \bar{\mu}.
\]

The total energy can be represented as

\[
\rho E = \rho \iota + \frac{1}{2} \rho |u|^2 = \rho \Psi + \rho \theta s + \frac{1}{2} \rho |u|^2.
\]

(78)

The definitions of the thermodynamic state variables are recollected here. The Helmholtz free energy density \( \Psi \), the local Helmholtz free energy density \( \Psi_{\text{loc}} \), the local internal energy density \( \iota_{\text{loc}} \), the internal energy density \( \iota \), the entropy density \( s \), and the local electrochemical potential \( \nu_{\text{loc}} \) are defined as

\[
\Psi(\rho, \theta, \nabla \rho) = \Psi_{\text{loc}}(\rho, \theta) + \frac{\lambda}{2 \rho} |\nabla \rho|^2,
\]

(79)

\[
\Psi_{\text{loc}}(\rho, \theta) = -a \rho + R \theta \log \left( \frac{\rho}{b - \rho} \right) - C_v \theta \log \left( \frac{\theta}{\theta_{\text{ref}}} \right) + C_v \theta,
\]

(80)

\[
\iota = \iota_{\text{loc}} + \frac{\lambda}{2 \rho} |\nabla \rho|^2,
\]

(81)

\[
\iota_{\text{loc}} = -a \rho + C_v \theta,
\]

(82)

\[
s = -R \log \left( \frac{\rho}{b - \rho} \right) + C_v \log \left( \frac{\theta}{\theta_{\text{ref}}} \right),
\]

(83)

\[
\nu_{\text{loc}} = -2a \rho + R \theta \log \left( \frac{\rho}{b - \rho} \right) + \frac{R \theta b}{b - \rho} - C_v \theta \log \left( \frac{\theta}{\theta_{\text{ref}}} \right) + C_v \theta.
\]

(84)
3.2 Dimensionless form of the Navier-Stokes-Korteweg equations

In this section, we perform dimensional analysis of the Navier-Stokes-Korteweg equations using the MLTΘ system. The reference scale of mass, length, time, and temperature are denoted as \( M_0, L_0, T_0, \) and \( \theta_0. \) We may obtain the dimensionless quantities denoted with a superscript *:

\[
\begin{align*}
  x &= L_0 x^*, \quad t = T_0 t^*, \quad \rho = \frac{M_0}{L_0^3} \rho^*, \quad \theta = \theta_0 \theta^*, \quad u = \frac{L_0}{T_0} u^*, \\
  p &= \frac{M_0}{L_0 T_0^2} p^*, \quad \lambda = \frac{L_0^2}{M_0 T_0^2} \lambda^*, \quad \bar{\mu} = \frac{M_0}{L_0 T_0} \bar{\mu}^*, \quad \tau = \frac{M_0}{T_0^2 L_0} \tau^*, \\
  \varsigma &= \frac{M_0}{T_0^2 L_0} \varsigma^*, \quad b = \frac{L_0}{T_0^2} b^*, \quad \kappa = \frac{M_0 L_0}{\theta_0 T_0^3} \kappa^*, \quad E = \frac{L_0^2}{T_0^2} E^*, \\
  q &= \frac{M_0}{T_0^3} q^*, \quad \Pi = \frac{M_0}{T_0^3} \Pi^*, \quad r = \frac{L_0^2}{T_0^3} r^*, \quad s = \frac{L_0^2}{T_0^2 \theta_0} s^*. \quad (85)
\end{align*}
\]

With the above dimensionless variables, the dimensionless balance equations can be written as

\[
\begin{align*}
  \frac{M_0}{T_0^3 L_0^3} \left( \frac{\partial \rho^*}{\partial t^*} + \nabla^* \cdot (\rho^* u^*) \right) &= 0, \\
  \frac{M_0}{T_0^2 L_0^2} \left( \frac{\partial (\rho^* u^*)}{\partial t^*} + \nabla^* \cdot (\rho^* u^* \otimes u^*) + \nabla^* p^* - \nabla^* \cdot \tau^* - \nabla^* \cdot \varsigma^* - \rho^* b^* \right) &= 0, \\
  \frac{M_0}{T_0^3 L_0} \left( \frac{\partial (\rho^* E^*)}{\partial t^*} + \nabla^* \cdot ((\rho^* E^* + p^*) u^*) - (\tau^* + \varsigma^*) u^* \right) + \nabla^* \cdot q^* + \nabla^* \cdot \Pi^* - \rho^* b^* u^* - \rho^* r^* &= 0.
\end{align*}
\]

The constitutive relations can be rescaled as

\[
\begin{align*}
  p^* &= R b \frac{L_0 T_0^2 \theta_0 \rho^* \theta^*}{b L_0^3 - M_0 \rho^*} - a \frac{M_0 T_0^2}{L_0^5} \rho^* \rho^2, \\
  \tau^* &= \bar{\mu}^* \left( \nabla^* u^* + \nabla^* u^* T \right) - \frac{2}{3} \bar{\mu}^* \nabla^* \cdot u^* I, \\
  \varsigma^* &= -\lambda^* \nabla^* \rho^* \otimes \nabla^* \rho^* + \left( \lambda^* \rho^* \Delta^* \rho^* + \frac{\lambda^*}{2} |\nabla^* \rho^*|^2 \right) I, \\
  q^* &= -\kappa^* \nabla^* \theta^*, \\
  s^* &= -\frac{R T_0^3 \theta_0}{L_0^2} \log \left( \frac{M_0 \rho^*}{L_0^3 b - M_0 \rho^*} \right) + \frac{C_v T_0^3 \theta_0}{L_0^3} \log \left( \frac{\theta_0 \theta^*}{\theta_{ref}} \right), \\
  \Pi^* &= \lambda^* \rho^* \nabla^* \cdot u^* \nabla^* \rho^*.
\end{align*}
\]
The dimensionless viscosity coefficient \( \bar{\mu}^* = \frac{L_0 T_0 \bar{\mu}}{M_0} \) measures the ratio of the viscous force to the inertial force; the dimensionless capillarity coefficient \( \lambda^* = \frac{M_0 T_0^2 \lambda}{L_0^2} \) measures the ratio of the surface tension to the inertia force. Hence, the two coefficients can be represented in terms of the Reynolds number Re and the Weber number We as

\[
\bar{\mu}^* = \frac{1}{\text{Re}}, \quad \lambda^* = \frac{1}{\text{We}}.
\]

The capillarity number \( \text{Ca} \), which measures the relative effect of the viscous force against the surface tension, is defined as

\[
\text{Ca} = \frac{\text{We}}{\text{Re}}.
\]

The Bond number \( \text{Bo} \) measures the ratio of the body force to the surface tension and it is defined as

\[
\text{Bo} = |b^*| \text{We}.
\]

There is one standard relation in thermodynamics relating the heat capacity at constant volume \( C_v \) and the universal gas constant \( R \):

\[
C_v = \frac{R}{\gamma - 1},
\]

wherein \( \gamma \) is the heat capacity ratio. Hence, we can denote

\[
\frac{C_v}{R} = \frac{1}{\gamma - 1}.
\]

**Remark 6.** *The value of \( \gamma \) is related to the degrees-of-freedom of the gas molecule. For example, \( \gamma \) for water vapor is 1.33 [?].*

If the reference scales are chosen as

\[
\frac{M_0}{L_0^3} = b, \\
\frac{M_0}{L_0 T_0^2} = ab^2, \\
\theta_0 = \theta_{\text{crit}} = \frac{8ab}{27R},
\]

33
and the reference temperature is picked as

$$\theta_{\text{ref}} = \theta_{\text{crit}},$$

the dimensionless Navier-Stokes-Korteweg equations can be written as

$$\frac{\partial \rho^*}{\partial t^*} + \nabla^* \cdot (\rho^* \mathbf{u}^*) = 0,$$  \hspace{1cm} \text{(86)}

$$\frac{\partial (\rho^* \mathbf{u}^*)}{\partial t^*} + \nabla^* \cdot (\rho^* \mathbf{u}^* \otimes \mathbf{u}^*) + \nabla^* p^* - \nabla^* \cdot \mathbf{\tau}^* - \nabla^* \cdot \mathbf{\varsigma}^* - \rho^* \mathbf{b}^* = 0,$$  \hspace{1cm} \text{(87)}

$$\frac{\partial (\rho^* E^*)}{\partial t^*} + \nabla^* \cdot ((\rho^* E^* + p^*) \mathbf{u}^* - (\mathbf{\tau}^* + \mathbf{\varsigma}^*) \mathbf{u}^*) + \nabla^* \cdot \mathbf{q}^* + \nabla^* \cdot \Pi^*
- \rho^* \mathbf{b}^* \mathbf{u}^* - \rho^* \mathbf{r}^* = 0,$$  \hspace{1cm} \text{(88)}

wherein,

$$p^* = \frac{8\theta^* \rho^*}{27(1 - \rho^*)} - \rho^{*2},$$  \hspace{1cm} \text{(89)}

$$\mathbf{\tau}^* = \frac{1}{\text{Re}} \left( \nabla^* \mathbf{u}^* + \nabla^* \mathbf{u}^{*T} - \frac{2}{3} \nabla^* \cdot \mathbf{u}^* \mathbf{I} \right),$$  \hspace{1cm} \text{(90)}

$$\mathbf{\varsigma}^* = \frac{1}{\text{We}} \left( \left( \rho^* \Delta^* \rho^* + \frac{1}{2} |\nabla^* \rho^*|^2 \right) \mathbf{I} - \nabla^* \rho^* \otimes \nabla^* \rho^* \right),$$  \hspace{1cm} \text{(91)}

$$\mathbf{q}^* = -\kappa^* \nabla^* \theta^*,$$  \hspace{1cm} \text{(92)}

$$\Pi^* = \frac{1}{\text{We}} \rho^* \nabla^* \cdot \mathbf{u}^* \nabla^* \rho^*,$$  \hspace{1cm} \text{(93)}

$$\text{Re} = \frac{L_0 b \sqrt{a b}}{\mu},$$  \hspace{1cm} \text{(94)}

$$\text{We} = \frac{a L_0^2}{\lambda}.$$  \hspace{1cm} \text{(95)}

Likewise, the thermodynamic state variables (79)-(84) can be rescaled as

$$\Psi^* = \Psi_{\text{loc}}^*(\rho, \theta) + \frac{1}{\text{We}} \frac{1}{2 \rho^*} |\nabla^* \rho^*|^2,$$  \hspace{1cm} \text{(96)}

$$\Psi_{\text{loc}}^*(\rho, \theta) = -\rho^* + \frac{8}{27} \theta^* \log \left( \frac{\rho^*}{1 - \rho^*} \right) - \frac{8}{27(\gamma - 1)} \theta^* \log(\theta^*) + \frac{8}{27(\gamma - 1)} \theta^*,$$  \hspace{1cm} \text{(97)}

$$\iota^* = \iota_{\text{loc}}^* + \frac{1}{2 \text{We}} \rho^* |\nabla^* \rho^*|^2,$$  \hspace{1cm} \text{(98)}

$$\iota_{\text{loc}}^* = -\rho^* + \frac{8}{27(\gamma - 1)} \theta^*,$$  \hspace{1cm} \text{(99)}

$$\nu_{\text{loc}}^* = -2\rho^* + \frac{8\theta^*}{27(1 - \rho^*)} + \frac{8}{27} \theta^* \log \left( \frac{\rho^*}{1 - \rho^*} \right).$$
\[ s^* = -\frac{8}{27} \log \left( \frac{\rho^*}{1 - \rho^*} \right) + \frac{8}{27(\gamma - 1)} \log (\theta^*). \] (101)

Henceforth, we will restrict our discussions to the dimensionless form, and the superscript * will be omitted for simplicity.

### 3.3 Functional entropy variables

The mathematical entropy function \( H \) is defined to be

\[ H := -\rho s = \frac{8}{27} \rho \log \left( \frac{\rho}{1 - \rho} \right) - \frac{8}{27(\gamma - 1)} \rho \log (\theta). \] (102)

With this definition, the second law of thermodynamics can be written in terms of \( H \) as

\[ \frac{\partial H}{\partial t} + \nabla \cdot (H \mathbf{u}) - \nabla \cdot \left( \frac{\mathbf{q}}{\theta} \right) + \rho r = -\frac{1}{\theta} \mathbf{\tau} : \nabla \mathbf{u} - \frac{1}{\theta^2} \nabla \theta \cdot \mathbf{\kappa} \nabla \theta \leq 0. \]

In three dimensions, the conservation variables can be written as

\[ \mathbf{U}^T = [U_1, U_2, U_3, U_4, U_5] := [\rho, \rho u_1, \rho u_2, \rho u_3, \rho E]. \]

The classical entropy variables for the compressible Navier-Stokes equations are defined as the calculus derivatives of the mathematical entropy function \( H \) with respect to the conservation variables \( \mathbf{U} \). This definition of the entropy variables was understood as a pure algebraic change-of-variables, since the mathematical entropy function for the compressible Navier-Stokes equation is a function in terms of the conservation variables. In contrast, due to the constitutive relation (98), the temperature \( \theta \) for the van der Waals fluid model can be expressed in terms of the conservation variables as

\[ \theta = \frac{27(\gamma - 1)}{8} \left( \frac{U_5}{U_1} - \frac{U_2^2 + U_3^2 + U_4^2}{2U_1^2} - \frac{1}{2 \text{We} U_1} |\nabla U_1|^2 + U_1 \right). \]

The above relation includes a non-local gradient-squared term. This fact suggests that when taking derivatives of the temperature with respect to conservation variables, the derivation should be taken in the functional setting. Therefore, for the Navier-Stokes-Korteweg
equations, the entropy variables $\mathbf{V}$ are defined as the functional derivatives:

$$
\mathbf{V} = \frac{\delta H}{\delta \mathbf{U}} = [V_1, V_2, V_3, V_4, V_5]^T = \left[ \frac{\delta H}{\delta U_1}, \frac{\delta H}{\delta U_2}, \frac{\delta H}{\delta U_3}, \frac{\delta H}{\delta U_4}, \frac{\delta H}{\delta U_5} \right]^T.
$$

Given the test functions $\delta \mathbf{v} = [\delta v_1, \delta v_2, \delta v_3, \delta v_4, \delta v_5]^T$, the entropy variables $\mathbf{V}$ are represented as linear operators acting on the test functions:

$$
\begin{align*}
V_1[\delta v_1] &= \frac{1}{\theta} \left( -2\rho + \frac{8}{27} \theta \log \left( \frac{\rho}{1-\rho} \right) - \frac{8}{27(\gamma-1)} \theta \log (\theta) + \frac{8}{27(\gamma-1)} \theta \right. \\
&\quad \left. + \frac{8\theta}{27(1-\rho)} - \frac{|\mathbf{u}|^2}{2} \right) \delta v_1 + \frac{1}{\text{We}\theta} \nabla \rho \cdot \nabla \delta v_1, \\
V_2[\delta v_2] &= \frac{u_1}{\theta} \delta v_2, \\
V_3[\delta v_3] &= \frac{u_2}{\theta} \delta v_3, \\
V_4[\delta v_4] &= \frac{u_3}{\theta} \delta v_4, \\
V_5[\delta v_5] &= -\frac{1}{\theta} \delta v_5.
\end{align*}
$$

Remark 7. The local Helmholtz free energy $\rho \Psi_{\text{loc}}$ can be regarded as a function of $\rho$ and $\theta$. Taking derivatives of $\rho \Psi_{\text{loc}}$ gives

$$
\begin{align*}
H &= \frac{\partial (\rho \Psi_{\text{loc}})}{\partial \theta}, \\
\nu_{\text{loc}} &= \frac{\partial (\rho \Psi_{\text{loc}})}{\partial \rho}.
\end{align*}
$$

Remark 8. In Section 2.4.2, we introduced the local electrochemical potential $\nu_{\text{loc}}$, defined as:

$$
\nu_{\text{loc}} = \frac{\partial (\rho \Psi_{\text{loc}})}{\partial \rho} = \Psi_{\text{loc}} + \rho \frac{\partial \Psi_{\text{loc}}}{\partial \rho}.
$$

We define the global electrochemical potential $\nu$ by generalizing the partial derivative in the above formula to the functional derivative:

$$
\nu[\delta v_1] := \Psi[\delta v_1] + \rho \frac{\delta \Psi}{\delta \rho} [\delta v_1]
$$

$$
= \left( -2\rho + \frac{8}{27} \theta \log \left( \frac{\rho}{1-\rho} \right) - \frac{8}{27(\gamma-1)} \theta \log (\theta) + \frac{8}{27(\gamma-1)} \theta \\
+ \frac{8\theta}{27(1-\rho)} \right) \delta v_1 + \frac{1}{\text{We}\theta} \nabla \rho \cdot \nabla \delta v_1.
$$
\[ = \nu_{\text{tot}} \delta v_1 + \frac{1}{\text{We}} \nabla \rho \cdot \nabla \delta v_1. \]

Interestingly, with this definition, the entropy variable \( V_1 \) can be written as

\[ V_1[\delta v_1] = \frac{1}{\theta} \left( \nu - \frac{|u|^2}{2} \right) [\delta v_1]. \]

Consequently, the entropy variables \( V \) can be compactly represented as

\[
V = \frac{1}{\theta} \begin{bmatrix}
\nu - \frac{|u|^2}{2} \\
u_1 \\
u_2 \\
u_3 \\
-1
\end{bmatrix}.
\] (108)

The expression (108) formally coincides with the definition of the entropy variables for the perfect gas model. However, the entropy variables here should be understood as linear operators in the dual spaces of the conservation variables. The expression (108) also hints that the formulation of the entropy variables is invariant under different choices of the Helmholtz free energy functional.

**Theorem 3.** The action of entropy variables \( V \) on the Navier-Stokes-Korteweg equations recovers the Clausius-Duhem inequality.

**Proof.** Testing the entropy variables \( V \) with the time derivative terms leads to

\[ V \left[ \frac{\partial U}{\partial t} \right] = \frac{\delta H}{\delta U} \left[ \frac{\partial U}{\partial t} \right] = \frac{\partial H}{\partial t} \] (109)

Choosing the test functions as the advective fluxes results in

\[
V \begin{bmatrix}
\nabla \cdot (\rho u) \\
\nabla \cdot (\rho u \otimes u) + \nabla p \\
\n\nabla \cdot (\rho E u + pu)
\end{bmatrix} = \nabla \cdot (H u)
\]
\[
+ \frac{1}{\text{We} \theta} \left( \nabla u : \nabla \rho \otimes \nabla \rho + \frac{1}{2} |\nabla \rho|^2 \nabla \cdot u + \rho \nabla \rho \cdot \nabla (\nabla \cdot u) \right).
\]

(110)

Taking the test functions as the terms related to the capillarity leads to

\[
\begin{bmatrix}
0 \\
-\nabla \cdot \varsigma \\
-\nabla \cdot (\varsigma u) + \nabla \cdot \Pi
\end{bmatrix}
\]

\[
= -\frac{1}{\text{We} \theta} \left( \nabla u : \nabla \rho \otimes \nabla \rho + \frac{1}{2} |\nabla \rho|^2 \nabla \cdot u + \rho \nabla \rho \cdot \nabla (\nabla \cdot u) \right).
\]

(111)

Combing (110)-(111) yields

\[
\begin{bmatrix}
\nabla \cdot (\rho u) \\
\nabla \cdot (\rho u \otimes u) + \nabla p - \nabla \cdot \varsigma \\
\nabla \cdot (\rho E u + p u) - \nabla \cdot (\varsigma u) + \nabla \cdot \Pi
\end{bmatrix}
\]

\[
= \nabla \cdot (Hu).
\]

(112)

Testing the entropy variables against the viscous flux gives

\[
\begin{bmatrix}
0 \\
-\nabla \cdot \tau \\
-\nabla \cdot (\tau u)
\end{bmatrix}
\]

\[
= \frac{1}{\theta} \theta : \nabla u.
\]

(113)

The action of entropy variables on the heat flux, the heat source, and the body force yields

\[
\begin{bmatrix}
0 \\
-\rho b \\
\nabla \cdot q - \rho u \cdot b - \rho r
\end{bmatrix}
\]

\[
= -\nabla \cdot \left( \frac{q}{\theta} \right) + \frac{\rho r}{\theta} + \frac{\nabla \theta \cdot \kappa \nabla \theta}{\theta^2}.
\]

(114)
Combing the relations (109), (112), (113), and (114) leads to

\[
\frac{\partial H}{\partial t} + \nabla \cdot (H \mathbf{u}) - \nabla \cdot \left( \frac{q}{\theta} \right) + \frac{\rho r}{\theta} = -\frac{\nabla \theta \cdot \kappa \nabla \theta}{\theta^2} - \frac{1}{\theta} \tau : \nabla \mathbf{u},
\]

or equivalently,

\[
\frac{\partial (\rho s)}{\partial t} + \nabla \cdot (\rho s \mathbf{u}) + \nabla \cdot \left( \frac{q}{\theta} \right) - \frac{\rho r}{\theta} = \frac{\nabla \theta \cdot \kappa \nabla \theta}{\theta^2} + \frac{1}{\theta} \tau : \nabla \mathbf{u}.
\]

This is exactly the dissipation relation for the Navier-Stokes-Korteweg equations.

3.4 An alternative statement of the strong problem

Theorem 3 suggests that a weak formulation for the Navier-Stokes-Korteweg equations will satisfy the Clausius-Duhem inequality weakly as long as the entropy variables $V$ are in the test function spaces. For the compressible Navier-Stokes equations, one may rewrite the equation in terms of the entropy variables $V$, since the mapping between $U$ and $V$ is purely algebraic. By using the Bubnov-Galerkin method, the entropy variables are enforced in the test function spaces, and consequently one can prove the entropy stability for the finite element formulation. This approach has been adopted for constructing entropy stable finite element formulations for a variety of problems [?, ?, ?, ?]. However, for the van der Waals fluid, there is an additional difficulty coming from the differential relation in the definition of $V_1$ in (103). The classical approach becomes nonviable, since there is a second-order differential operator in the definition of $V_1$, and inverting a differential operator is not a straightforward task. Inspired from the form of $V_1$, we introduce a new independent variable and couple it with the conservation laws by replacing the pressure. Hence, we may derive a new system of equations, which is a consistent statement of the original strong problem. In doing so, the entropy variable $V_1$ is weakly enforced in the test function space for the mass balance equation, and we can prove entropy stability for the weak problem. To derive the alternative statement of the Navier-Stokes-Korteweg equations, we introduce the auxiliary variable $V$ here as

\[
V := \frac{1}{\theta} \left( \nu_{loc} - \frac{|\mathbf{u}|^2}{2} \right) - \frac{1}{\text{We}} \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right).
\]

Recall that the local electrochemical potential is related to the thermodynamic pressure by

\[
\nu_{loc} = \frac{p}{\rho} + \Psi_{loc}.
\]
Hence, the auxiliary variable $V$ can be rewritten as

$$V = \frac{1}{\theta} \left( \frac{p}{\rho} + \Psi_{\text{loc}} - \frac{|u|^2}{2} \right) - \frac{1}{\text{We}} \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right).$$

Rearranging terms in the above relation yields

$$p = \rho V \theta - \rho \Psi_{\text{loc}} + \frac{\rho |u|^2}{2} + \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right). \quad (116)$$

The above relation is an equivalent expression of the van der Waals equation of state (66) in terms of the newly introduced auxiliary variable $V$. Taking gradient at both sides of (116), we have

$$\nabla p = \nabla \left( \rho V \theta + \frac{\rho |u|^2}{2} + \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right) - \nabla \left( \rho \Psi_{\text{loc}} \right)$$

$$= \nabla \left( \rho V \theta + \frac{\rho |u|^2}{2} + \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right) - \frac{\partial (\rho \Psi_{\text{loc}})}{\partial \rho} \nabla \rho - \frac{\partial (\rho \Psi_{\text{loc}})}{\partial \theta} \nabla \theta$$

$$= \nabla \left( \rho V \theta + \frac{\rho |u|^2}{2} + \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right) - \nu_{\text{loc}} \nabla \rho - H \nabla \theta$$

$$= \nabla \left( \rho V \theta + \frac{\rho |u|^2}{2} + \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right)$$

$$- \left( V \theta + \frac{|u|^2}{2} + \frac{1}{\text{We}} \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right) \nabla \rho - H \nabla \theta. \quad (117)$$

Using (116), the term $\rho E + p$ can be reorganized as

$$\rho E + p = \rho \Psi_{\text{loc}} - \theta H + \frac{1}{2 \text{We}} |\nabla \rho|^2 + \frac{1}{2} \rho |u|^2$$

$$+ \rho V \theta + \frac{1}{2} \rho |u|^2 - \rho \Psi_{\text{loc}} + \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right)$$

$$= \rho V \theta - \theta H + \frac{1}{2 \text{We}} |\nabla \rho|^2 + \rho |u|^2 + \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right). \quad (118)$$

Making use of (117) and (118), the pressure force $\nabla p$ and the power expenditure of pressure $\nabla \cdot (\rho u)$ can be consistently represented in terms of $V$. Then the original strong problem (86)-(88) can be rewritten as

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho u) = 0, \quad (119)$$

$$\frac{\partial (\rho u)}{\partial t} + \nabla \cdot (\rho u \otimes u) + \nabla \left( \rho V \theta + \frac{\rho |u|^2}{2} + \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right)$$
\[- \left( \nabla \theta + \frac{|\mathbf{u}|^2}{2} + \frac{1}{\text{We}} \theta \nabla \cdot \left( \nabla \frac{\rho}{\theta} \right) \right) \nabla \rho - H \nabla \theta - \nabla \cdot \mathbf{\tau} - \nabla \cdot \mathbf{\varsigma} = \rho \mathbf{b}, \tag{120}\]

\[\frac{\partial (\rho E)}{\partial t} + \nabla \cdot \left( \left( \rho \nabla \theta - \theta H + \frac{1}{2 \text{We}} |\nabla \rho|^2 + \rho |\mathbf{u}|^2 + \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right) \mathbf{u} \right) - \nabla \cdot ((\mathbf{\tau} + \mathbf{\varsigma}) \mathbf{u}) + \nabla \cdot \mathbf{q} + \nabla \cdot \mathbf{\Pi} = \rho \mathbf{b} \cdot \mathbf{u} + \rho r, \tag{121}\]

\[V = \frac{1}{\theta} \left( \nu_{\text{loc}} - \frac{|\mathbf{u}|^2}{2} \right) - \frac{1}{\text{We}} \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right). \tag{122}\]

The equation (122) defines the auxiliary variable $V$. Based on our derivation, the new balance equations (119)-(121), together with the auxiliary variable (122), is equivalent to the original Navier-Stokes-Korteweg equations.

### 3.5 Weak formulation

In this section, we construct a weak formulation based on the alternative statement (119)-(122). In the weak formulation, we solve for six unknowns in three dimensions. The set of variables is denoted as

\[
\mathbf{Y} = \begin{bmatrix}
Y_1 \\
Y_2 \\
Y_3 \\
Y_4 \\
Y_5 \\
Y_6
\end{bmatrix} := \begin{bmatrix}
\rho \\
u_1 \\
u_2 \\
u_3 \\
-\frac{1}{\theta} \\
V
\end{bmatrix}. \tag{123}
\]

Let $\mathcal{V}_1$ be the trial solution space for $Y_1 = \rho$ and $Y_6 = V$; $\mathcal{V}_2$ be the trial solution space for $Y_{i+1} = u_i/\theta$, $i = 1, 2, 3$; $\mathcal{V}_3$ be the trial solution space for $Y_5 = -1/\theta$. The test function spaces are taken to be identical to the corresponding trial solution spaces. The weak formulation can be stated as follows. Find $Y_1(t) = \rho(t) \in L^2(0, T; \mathcal{V}_1) \cap H^1(0, T; L^2(\Omega))$, $Y_{i+1}(t) = u_i(t)/\theta(t) \in L^2(0, T; \mathcal{V}_2) \cap H^1(0, T; L^2(\Omega))$ for $i = 1, 2, 3$, $Y_4(t) = -1/\theta(t) \in L^2(0, T; \mathcal{V}_3) \cap H^1(0, T; L^2(\Omega))$, $Y_5(t) = -1/\theta(t) \in L^2(0, T; \mathcal{V}_3) \cap H^1(0, T; L^2(\Omega))$, $Y_6(t) = V \in L^2(0, T; \mathcal{V}_6) \cap H^1(0, T; L^2(\Omega))$. 

41
and $Y_6(t) = V \in L^2(0, T; \mathcal{V}_1)$, such that

$$
\left( w_1, \frac{\partial \rho}{\partial t} \right)_\Omega - (\nabla w_1, \rho u)_\Omega = 0, \quad \forall w_1 \in \mathcal{V}_1,
$$

(124)

$$
\left( w, \frac{\partial (\rho u)}{\partial t} \right)_\Omega - (\nabla w, \rho u \otimes u)_\Omega - \left( \nabla \cdot w, \rho V \theta + \frac{1}{2} \rho |u|^2 + \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right)_\Omega
$$

$$
- \left( w, \left( V \theta + \frac{|u|^2}{2} + \frac{1}{\text{We}} \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right) \nabla \rho \right)_\Omega - (w, H \nabla \theta)_\Omega + (\nabla w, \tau)_\Omega + (\nabla w, \varsigma)_\Omega
$$

$$
= (w, \rho b)_\Omega, \quad \forall w = (w_2; w_3; w_4)^T \in (\mathcal{V}_2)^3,
$$

(125)

$$
\left( w_5, \frac{\partial (\rho E)}{\partial t} \right)_\Omega = \left( \nabla w_5, \left( \rho V \theta - \theta H + \frac{1}{2 \text{We}} |\nabla \rho|^2 + \rho |u|^2 + \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right) u \right)_\Omega
$$

$$
+ (\nabla w_5, \tau u)_\Omega + (\nabla w_5, \varsigma u)_\Omega - (\nabla w_5, q)_\Omega - (\nabla w_5, \Pi)_\Omega
$$

$$
= (w_5, \rho b \cdot u)_\Omega + (w_5, \rho r)_\Omega, \quad \forall w_5 \in \mathcal{V}_3,
$$

(126)

$$
(w_6, V)_\Omega = \left( w_6, \frac{1}{\theta} \left( \nu_{\text{loc}} - \frac{|u|^2}{2} \right) \right)_\Omega + \left( \nabla w_6, \frac{1}{\text{We} \theta} \nabla \rho \right)_\Omega, \quad \forall w_6 \in \mathcal{V}_1,
$$

(127)

with $\rho(0) = \rho_0$, $u(0)/\theta(0) = u_0/\theta_0$, and $-1/\theta(0) = -1/\theta_0$ in $\Omega$.

Comparing (127) with (103), one may find that the auxiliary variable $V$ is identical to the entropy variable $V_1$ in the weak formulation. Therefore, in the set of variables (123), we are actually solving for the entropy variables $\mathbf{V}$ together with density $\rho$, which is the conjugate variable to $V_1 = V$. By choosing the test function and trial solution spaces identical for the equations (119) and (122), the entropy variable $V_1$ is weakly enforced to be in the test function space for the mass balance equation. This is a key ingredient in the proof of the following theorem.

**Theorem 4.** Sufficiently smooth weak solutions of the problem (124)-(127) verify the second law of thermodynamics, i.e.,

$$
\int_{\Omega} \left( \frac{\partial H}{\partial t} + \nabla \cdot (Hu) - \nabla \cdot \left( \frac{q}{\theta} + \frac{\rho r}{\theta} \right) \right) dV_x = - \int_{\Omega} \frac{1}{\theta} \tau : \nabla u dV_x - \int_{\Omega} \frac{\nabla \theta \cdot \kappa \nabla \theta}{\theta^2} dV_x.
$$

(128)

**Proof.** Choosing $w_1 = V$ in (124) and $w_6 = \partial \rho / \partial t$ in (127) yields

$$
\left( V, \frac{\partial \rho}{\partial t} \right)_\Omega - (\nabla V, \rho u)_\Omega = 0,
$$

$$
\left( \frac{\partial \rho}{\partial t}, V \right)_\Omega = \left( \frac{\partial \rho}{\partial t}, \frac{1}{\theta} \left( \nu_{\text{loc}} - \frac{|u|^2}{2} \right) \right)_\Omega + \left( \nabla \left( \frac{\partial \rho}{\partial t} \right), \frac{1}{\text{We} \theta} \nabla \rho \right)_\Omega.
$$

42
Combing the above two relations leads to

\[
\int_{\Omega} \frac{\delta H}{\delta \rho} \left[ \frac{\partial (\rho u)}{\partial t} \right] dV_x = \left( \frac{\partial \rho}{\partial t} \cdot \frac{1}{\theta} \left( \nu_{\text{loc}} - \frac{|u|^2}{2} \right) \right) + \left( \nabla \left( \frac{\partial \rho}{\partial t} \right), \frac{1}{\text{We} \theta} \nabla \rho \right)_\Omega
\]

\[
= (\nabla V, \rho u)_\Omega. \quad (129)
\]

Taking \( w = u/\theta \) in (125) results in

\[
\int_{\Omega} \frac{\delta H}{\delta (\rho u)} \left[ \frac{\partial (\rho u)}{\partial t} \right] dV_x = \left( \frac{u}{\theta}, \frac{\partial (\rho u)}{\partial t} \right)_\Omega = \left( \nabla \left( \frac{u}{\theta} \right), \rho u \otimes u \right)_\Omega
\]

\[
+ \left( \nabla \cdot \left( \frac{u}{\theta} \right), \rho V \theta + \frac{1}{2} \rho |u|^2 + \frac{1}{\text{We} \theta} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right)_\Omega
\]

\[
+ \left( \frac{u}{\theta}, \left( V \theta + \frac{|u|^2}{2} + \frac{1}{\text{We} \theta} \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right) \nabla \rho \right)_\Omega
\]

\[
+ \left( \frac{u}{\theta}, H \nabla \theta \right)_\Omega - \left( \nabla \left( \frac{u}{\theta} \right), \tau \right)_\Omega - \left( \nabla \left( \frac{u}{\theta} \right), s \right)_\Omega
\]

\[
+ \left( \frac{u}{\theta}, \rho b \right)_\Omega. \quad (130)
\]

Choosing \( w_5 = -1/\theta \) in (126) yields

\[
\int_{\Omega} \frac{\delta H}{\delta (\rho E)} \left[ \frac{\partial (\rho E)}{\partial t} \right] dV_x = \left( -\frac{1}{\theta}, \frac{\partial (\rho E)}{\partial t} \right)_\Omega = \left( \nabla \left( \frac{1}{\theta} \right), \rho V \theta - \theta H \right)_\Omega
\]

\[
+ \frac{1}{2 \text{We}} |\nabla \rho|^2 + \rho |u|^2 + \frac{1}{\text{We} \theta} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right)_\Omega
\]

\[
+ \left( \nabla \left( \frac{1}{\theta} \right), \tau u \right)_\Omega + \left( \nabla \left( \frac{1}{\theta} \right), \varsigma u \right)_\Omega
\]

\[
+ \left( \frac{1}{\theta}, \nabla \cdot q \right)_\Omega - \left( \nabla \left( \frac{1}{\theta} \right), \Pi \right)_\Omega - \left( \frac{1}{\theta}, \rho b_\cdot u \right)_\Omega
\]

\[
- \left( \frac{1}{\theta}, \rho r \right)_\Omega \quad (131)
\]

Grouping all terms in (129)-(131) involving \( V \), one has

\[
(\nabla V, \rho u)_\Omega + \left( \nabla \cdot \left( \frac{u}{\theta} \right), \rho V \theta \right)_\Omega + \left( \frac{u}{\theta}, V \theta \nabla \rho \right)_\Omega - \left( \nabla \left( \frac{1}{\theta} \right), V \theta \rho u \right)_\Omega
\]

\[
= \int_{\Omega} \nabla \cdot (\rho V u) dV_x = \int_{\partial \Omega} \rho V u \cdot ndA_x = 0. \quad (132)
\]
Summing all terms in (129)-(131) involving $H$ yields
\[
\left( \frac{u}{\theta}, H \nabla \theta \right)_\Omega + \left( \nabla \left( \frac{1}{\theta} \right), \theta H u \right)_\Omega = \left( \frac{u}{\theta}, H \nabla \theta \right)_\Omega - \left( \frac{1}{\theta}, \nabla (\theta H u) \right)_\Omega
= - \int_\Omega \nabla \cdot (H u) \, dV_x. \tag{133}
\]

Next, collecting all terms in (129)-(131) explicitly involving $\text{We}$, we have
\[
\left( \nabla \cdot \left( \frac{u}{\theta} \right), \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \right)_\Omega + \left( \frac{u}{\theta}, \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) \nabla \rho \right)_\Omega
- \left( \nabla \left( \frac{1}{\theta} \right), \frac{1}{\text{We}} \rho \theta \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) u \right)_\Omega - \left( \nabla \left( \frac{1}{\theta} \right), \frac{1}{2 \text{We}} |\nabla \rho|^2 u \right)_\Omega
= \int_\Omega \frac{1}{\text{We}} \nabla \cdot (\rho u) \nabla \cdot \left( \frac{\nabla \rho}{\theta} \right) - \frac{1}{2 \text{We}} \nabla \left( \frac{1}{\theta} \right) \cdot u |\nabla \rho|^2 dV_x
- \int_\Omega \frac{1}{\text{We}} \nabla \left( \nabla \cdot (\rho u) \right) \cdot \nabla \rho + \frac{1}{2 \text{We}} \nabla \cdot (u |\nabla \rho|^2) \, dV_x
= \int_\Omega -\frac{1}{\text{We}} \left( \frac{1}{2} |\nabla \rho|^2 \nabla \cdot u + \nabla \rho \otimes \nabla \rho : \nabla u + \rho \nabla \rho \cdot \nabla \left( \nabla \cdot u \right) \right) dV_x. \tag{134}
\]

Combining all the terms in (129)-(131) including the Korteweg stress $\varsigma$ and the interstitial working, we have
\[
- \left( \nabla \left( \frac{u}{\theta} \right), \varsigma \right)_\Omega + \left( \nabla \left( \frac{1}{\theta} \right), \varsigma u \right)_\Omega - \left( \nabla \left( \frac{1}{\theta} \right), \Pi \right)_\Omega
= - \left( \frac{1}{\theta}, \nabla \cdot \varsigma \right)_\Omega + \left( \frac{1}{\theta}, \nabla \cdot \Pi \right)_\Omega
= \int_\Omega \frac{1}{\text{We}} \left( \frac{1}{2} |\nabla \rho|^2 \nabla \cdot u + \nabla \rho \otimes \nabla \rho : \nabla u + \rho \nabla \rho \cdot \nabla \left( \nabla \cdot u \right) \right) dV_x. \tag{135}
\]

Making use of (132)-(135), the summation of (129)-(131) gives
\[
\int_\Omega \frac{\delta H}{\delta \rho} \left[ \frac{\partial \rho}{\partial t} \right] + \frac{\delta H}{\delta (\rho u)} \left[ \frac{\partial (\rho u)}{\partial t} \right] + \frac{\delta H}{\delta (\rho E)} \left[ \frac{\partial (\rho E)}{\partial t} \right] \, dV_x
= - \int_\Omega \nabla \cdot (H u) \, dV_x - \left( \nabla \left( \frac{u}{\theta} \right), \tau \right)_\Omega + \left( \nabla \left( \frac{1}{\theta} \right), \tau u \right)_\Omega + \left( \frac{1}{\theta}, \rho b \cdot u \right)_\Omega
- \left( \frac{1}{\theta}, \rho b \cdot u \right)_\Omega + \left( \frac{1}{\theta}, \nabla \cdot q \right)_\Omega - \left( \frac{1}{\theta}, \rho r \right)_\Omega
\]
\[
\left. \begin{align*}
\int_{\Omega} \nabla \cdot (H \mathbf{u}) \, dV_x & = \int_{\Omega} \frac{1}{\theta} \mathbf{\tau} : \nabla \mathbf{u} \, dV_x + \left( \frac{1}{\theta} \cdot \nabla \cdot \mathbf{q} \right)_\Omega - \left( \frac{1}{\theta} \cdot \rho r \right)_\Omega \\
& = \int_{\Omega} \nabla \cdot (H \mathbf{u}) \, dV_x - \int_{\Omega} \frac{1}{\theta} \mathbf{\tau} : \nabla \mathbf{u} \, dV_x + \int_{\Omega} \nabla \cdot \left( \frac{\mathbf{q}}{\theta} \right) + \frac{\mathbf{q} \cdot \nabla \theta}{\theta^2} - \frac{\rho r}{\theta} \, dV_x.
\end{align*}\]

The above equation implies
\[
\int_{\Omega} \left( \frac{\partial H}{\partial t} + \nabla \cdot (H \mathbf{u}) - \nabla \cdot \left( \frac{\mathbf{q}}{\theta} \right) + \frac{\rho r}{\theta} \right) \, dV_x = - \int_{\Omega} \frac{1}{\theta} \mathbf{\tau} : \nabla \mathbf{u} \, dV_x - \int_{\Omega} \frac{\nabla \theta \cdot \kappa \nabla \theta}{\theta^2} \, dV_x,
\]
which completes the proof of this theorem.

**Remark 9.** In our discussion, we assumed periodic boundary conditions. Under the periodic boundary conditions, the divergence terms in (128) are canceled out and the statement can be simplified as
\[
\int_{\Omega} \left( \frac{\partial H}{\partial t} + \rho r \right) \, dV_x = - \int_{\Omega} \frac{1}{\theta} \mathbf{\tau} : \nabla \mathbf{u} \, dV_x - \int_{\Omega} \frac{\nabla \theta \cdot \kappa \nabla \theta}{\theta^2} \, dV_x.
\]

Even though we proved the case with periodic boundary conditions, the proof of Theorem 4 can proceed under other boundary conditions, such as the no-slip boundary conditions for the velocity field and the heat flux boundary condition for the temperature field. The major difficulty comes from the non-homogeneous essential boundary conditions. If there are non-zero functions built in the trial solution spaces, we cannot choose the test function as the entropy variables and the technique in the above proof is no more viable. The same issue arises for the compressible Navier-Stokes equations [?]. This suggests that the strong imposition of Dirichlet type boundary conditions is not an entropy-dissipative approach. The recently developed weak imposition technique [?] may provide a solution to this issue.

### 3.6 Semi-discrete formulation

We perform spatial discretization of (119)-(122) by invoking the Galerkin method [?]. Let \( V_1^h \subset V_1, V_2^h \subset V_2, \) and \( V_3^h \subset V_3 \) be finite-dimensional function spaces, in which the superscript \( h \) denotes a mesh parameter. Then the spatial discretization of (119)-(122) can be stated as follows.

Find \( Y_1^h(t) = \rho^h(t) \in L^2(0,T;V_1^h) \cap H^1(0,T;L^2(\Omega)), \) \( Y_{i+1}^h(t) = u_{i+1}^h(t)/\theta^h(t) \in L^2(0,T;V_2^h) \cap H^1(0,T;L^2(\Omega)) \) for \( i = 1, 2, 3, \) \( Y_4^h(t) = -1/\theta^h(t) \in L^2(0,T;V_3^h) \cap H^1(0,T;L^2(\Omega)), \) and
\[ Y_6^h = V^h \in L^2(0,T;\mathcal{V}_3^h), \text{ such that} \]
\[
\begin{align*}
(w_h^i, \frac{\partial \rho^h}{\partial t})_\Omega - (\nabla w_h^i, \rho^h u^h)_\Omega &= 0, \quad \forall w_h^i \in \mathcal{V}_1^h, \\
(w_h, \frac{\partial (\rho^h u^h)}{\partial t})_\Omega - (\nabla w^h, \rho^h u^h \otimes u^h)_\Omega
- (\nabla \cdot w^h, \rho^h V^h \theta^h + \frac{1}{2} \rho^h |u^h|^2 + \frac{1}{We} \rho^h \theta^h \nabla \cdot \left( \frac{\nabla \rho^h}{\theta^h} \right))_\Omega
- (w^h, \left( V^h \theta^h + \frac{|u^h|^2}{2} + \frac{1}{We} \theta^h \nabla \cdot \left( \frac{\nabla \rho^h}{\theta^h} \right) \right) \nabla \rho^h)_\Omega
+ (\nabla w^h, \tau^h)_\Omega + (\nabla w^h, \varsigma^h)_\Omega = (w^h, \rho^h b)_\Omega, \\
\forall w^h = (w_2^h; w_3^h; w_4^h)^T \in (\mathcal{V}_2^h)^3, \\
\end{align*}
\]
(136)
\[
\begin{align*}
(w_5^h, \nabla \cdot (\rho^h E^h))_\Omega - (\nabla w_5^h, \left( \rho^h V^h \theta^h - \theta^h H^h + \frac{1}{2 \ We} |\nabla \rho^h|^2 + \rho^h |u^h|^2 \\
+ \frac{1}{We} \rho^h \theta^h \nabla \cdot \left( \frac{\nabla \rho^h}{\theta^h} \right) \right) u^h)_\Omega + (\nabla w_5^h, \tau^h u^h)_\Omega + (\nabla w_5^h, \varsigma^h u^h)_\Omega
- (\nabla w_5^h, q^h)_\Omega - (\nabla w_5^h, \Pi^h)_\Omega = (w_5^h, \rho^h b \cdot u^h)_\Omega + (w_5^h, \rho^h r)_\Omega, \quad \forall w_5^h \in \mathcal{V}_3^h, \\
(w_6^h, V^h)_\Omega = \left( w_6^h, \frac{1}{\theta^h} \left( \nu^h_{loc} - \frac{|u^h|^2}{2} \right) \right)_\Omega + \left( \nabla w_6^h, \frac{1}{We \theta^h} \nabla \rho^h \right)_\Omega, \quad \forall w_6^h \in \mathcal{V}_1^h, \\
\end{align*}
\]
(137)
(138)
(139)

with \( \rho^h(0) = \rho_0^h, u^h(0)/\theta^h(0) = u_0^h/\theta_0^h, \) and \(-1/\theta^h(0) = -1/\theta_0^h \) in \( \Omega \).

In the above formulation, \( \rho_0^h, u_0^h/\theta_0^h, \) and \(-1/\theta_0^h \) are \( L^2 \)-projections of \( \rho_0(x), u_0(x)/\theta_0(x) \), and \(-1/\theta_0(x) \) onto \( \mathcal{V}_1^h, \mathcal{V}_2^h, \) and \( \mathcal{V}_3^h \) respectively. Employing the same techniques used in the proof of Theorem 4, we can obtain the following theorem, which implies that the spatial discretization (136)-(139) is entropy dissipative.

**Theorem 5.** The solutions of the semi-discrete formulation (136)-(139) satisfy the second law of thermodynamics in the following sense.

\[
\int_\Omega \left( \frac{\partial H(\rho^h, \theta^h)}{\partial t} + \nabla \cdot (H(\rho^h, \theta^h) u^h) - \nabla \cdot \left( \frac{q^h}{\theta^h} \right) + \frac{\rho^h r}{\theta^h} \right) dV_x
= - \int_\Omega \frac{1}{\theta^h} \tau^h : \nabla u^h dV_x - \int_\Omega \frac{\nabla \theta^h \cdot \kappa \nabla \theta^h}{(\theta^h)^2} dV_x.
\]

**Remark 10.** In our implementation, the same discrete space \( \mathcal{V}^h \), up to the prescription of the boundary conditions, is used to approximate \( \mathcal{V}_1, \mathcal{V}_2, \) and \( \mathcal{V}_3 \). Specifically, the Non-Uniform Rational B-Spline (NURBS) basis functions are used to define \( \mathcal{V}^h \) as well as the geometry.
of the computational domain. This approach directly leads to the concept of isogeometric analysis [?].

3.7 The fully discrete formulation

In the preceding section, we have constructed an entropy-dissipative semi-discrete formulation. It remains to design discretizations of the time derivatives such that the dissipation property can be inherited in the time direction. In our previous work [?], we have successfully developed a suite of temporal schemes for the isothermal Navier-Stokes-Korteweg equations. For the thermal case, the difficulty comes from the term $\partial (\rho E)/\partial t$. If one uses the traditional jump operator to approximate the time derivative, it will be hard to estimate the dissipation of the resulting scheme. In this work, the total energy $\rho E$ is split into four parts:

$$
\rho E = \rho \Psi_{\text{loc}} - \theta H + \frac{1}{2} \rho |u|^2 + \frac{1}{2 \We} |\nabla \rho|^2,
$$

and the time approximation for each of the four parts will be carefully designed to ensure consistency and temporal dissipation. It is noteworthy that, in the design of the discrete scheme, the special quadrature rules developed in [? , ?] will be used repeatedly as a key technique. In the following text, we will first state the fully discrete scheme in Section 3.7.1. Following that, five preliminary lemmas are given in Section 3.7.2. The main results about the entropy-dissipation property and time accuracy are proven in Section 3.7.3.

3.7.1 The fully discrete scheme

To discretize the semi-discrete formulation, the time interval $\mathcal{I} = (0, T)$ is divided into $N_{ts}$ subintervals $\mathcal{I}_n = (t_n, t_{n+1}), n = 0, \ldots, N_{ts} - 1$, of size $\Delta t_n = t_{n+1} - t_n$. We use the notation

$$
\mathbf{Y}^h_n := \begin{bmatrix}
\rho^h_n; u^h_{1,n}; u^h_{2,n}; u^h_{3,n}; u^h_{5,n}; V^h_n
\end{bmatrix}^T
$$

(141)

to denote the fully discrete solutions at the time level $n$. The fully discrete primitive variables at the same time level can be represented in terms of $\mathbf{Y}^h_n$ as

$$
\rho^h_n = \rho^h(\mathbf{Y}^h_n) = Y^h_{1,n},
$$

$$
u^h_{i,n} = u^h_{i}(\mathbf{Y}^h_n) = -Y^h_{i+1,n}/Y^h_{5,n}, \quad i = 1, 2, 3,
$$

$$
\theta^h_n = \theta^h(\mathbf{Y}^h_n) = -1/Y^h_{5,n}.
$$
We define the jump of density, linear momentum, and total energy over each time step as

\[
\begin{align*}
\{\rho_n^h\} &:= \rho_{n+1}^h - \rho_n^h, \\
\{\rho_n^h u_n^h\} &:= \rho_{n+1}^h u_{n+1}^h - \rho_n^h u_n^h, \\
\{\rho_n^h E(\rho_n^h, u_n^h, \theta_n^h)\} &:= (\rho \Psi_{loc}(\rho_{n+\frac{1}{2}}^h, \theta_{n+\frac{1}{2}}^h) - (\rho \Psi_{loc}(\rho_{n+\frac{1}{2}}^h, \theta_n^h) \\
&+ (\rho \Psi_{loc}(\rho_{n+\frac{1}{2}}^h, \theta_n^h) - (\rho \Psi_{loc}(\rho_{n+\frac{1}{2}}^h, \theta_n^h) \\
&- \theta_n^{h+\frac{1}{2}}(H(\rho_{n+\frac{1}{2}}^h, \theta_{n+\frac{1}{2}}^h) - H(\rho_n^h, \theta_n^h)) \\
&- \frac{\theta_{n+1}^h - \theta_n^h}{2} \left(H(\rho_{n+\frac{1}{2}}^h, \theta_{n+\frac{1}{2}}^h) + H(\rho_n^h, \theta_n^h)\right) \\
&+ \frac{(\theta_{n+1}^h - \theta_n^h)^3}{12} \frac{\partial^2 H}{\partial \theta^2}(\rho_{n+\frac{1}{2}}^h, \theta_{n+\frac{1}{2}}^h) \\
&+ \frac{1}{2} \left(\rho_{n+1}^h |u_{n+1}^h|^2 - \rho_n^h |u_n^h|^2\right) \\
&+ \frac{1}{2} We \left(|\nabla \rho_{n+1}^h|^2 - |\nabla \rho_n^h|^2\right).
\end{align*}
\]

\textbf{Remark 11.} According to the energy split (140), the definition (144) can be rewritten as a summation of four jumps:

\[
\begin{align*}
\{\rho_n^h E(\rho_n^h, u_n^h, \theta_n^h)\} &= \{\rho_n^h \Psi_{loc}(\rho_n^h, \theta_n^h)\} - \{\theta_n^h H(\rho_n^h, \theta_n^h)\} + \left\{\frac{\rho_n^h}{2} |u_n^h|^2\right\} + \left\{\frac{1}{2} We |\nabla \rho_n^h|^2\right\},
\end{align*}
\]

wherein,

\[
\begin{align*}
\{\rho_n^h \Psi_{loc}(\rho_n^h, \theta_n^h)\} &:= (\rho \Psi_{loc}(\rho_{n+\frac{1}{2}}^h, \theta_{n+\frac{1}{2}}^h) - (\rho \Psi_{loc}(\rho_{n+\frac{1}{2}}^h, \theta_n^h) \\
&+ (\rho \Psi_{loc}(\rho_{n+\frac{1}{2}}^h, \theta_n^h) - (\rho \Psi_{loc}(\rho_{n+\frac{1}{2}}^h, \theta_n^h) \\
&- \theta_n^{h+\frac{1}{2}}(H(\rho_{n+\frac{1}{2}}^h, \theta_{n+\frac{1}{2}}^h) - H(\rho_n^h, \theta_n^h)) \\
&+ \frac{(\theta_{n+1}^h - \theta_n^h)^3}{12} \frac{\partial^2 H}{\partial \theta^2}(\rho_{n+\frac{1}{2}}^h, \theta_{n+\frac{1}{2}}^h) \\
&+ \frac{1}{2} \left(\rho_{n+1}^h |u_{n+1}^h|^2 - \rho_n^h |u_n^h|^2\right)
\end{align*}
\]

\[
\text{The definitions (146) and (147) are inspired by the fact that the summation of first-order partial derivatives approximates the total derivative. In (147), there is an additional third-order perturbation term, whose role will be revealed in Lemma 6. The jump operators for the}
\]

\[\text{ }
\]
kinetic energy and the surface energy follow the classical definition.

With the jump operators defined above, the fully discrete scheme is stated as follows. In each time step, given \( Y^h_n \) and the time step \( \Delta t_n \), find \( Y^h_{n+1} \) such that for all \( w_1^h \in \mathcal{V}^h \), \( w_2^h = (w_2^h; w_3^h; w_4^h)^T \in (\mathcal{V}^h)^3 \), \( w_5^h \in \mathcal{V}^h \), and \( w_6^h \in \mathcal{V}^h \),

\[
B^M(w_1^h; Y^h_{n+1}) := \left( w_1^h, \left[ \frac{\rho_n^h}{\Delta t_n} \right] \right) - \left( \nabla U, \rho_{n+\frac{1}{2}} u_{n+\frac{1}{2}, 1} \right) = 0, \tag{150}
\]

\[
B^U(w^h; Y^h_{n+1}) := \left( w^h, \left[ \frac{\rho_n^h}{\Delta t_n} \right] \right) - \left( \nabla U, \rho_{n+\frac{1}{2}} u_{n+\frac{1}{2}, 1} \otimes u_{n+\frac{1}{2}} \right) \tag{151}
\]

\[
\left( \nabla \cdot w^h, \rho_{n+\frac{1}{2}} V^h + \frac{1}{2} \rho_{n+\frac{1}{2}} |u_{n+\frac{1}{2}}|^2 + \frac{1}{2 \text{We}} \rho_{n+\frac{1}{2}} \frac{\theta^h}{\theta_{n+\frac{1}{2}}} \nabla \cdot \left( \frac{\nabla \rho_{n+\frac{1}{2}}}{\theta_{n+\frac{1}{2}}} \right) \right) \tag{152}
\]

\[
B^E(w_5^h; Y^h_{n+1}) := \left( w_5^h, \left[ \frac{\rho_n^h E(\rho_n^h, u_n^h, \theta_n^h)}{\Delta t_n} \right] \right) - \left( \nabla U, \left( \rho_{n+\frac{1}{2}} V^h + \frac{1}{2 \text{We}} \frac{\theta^h}{\theta_{n+\frac{1}{2}}} \nabla \rho_{n+\frac{1}{2}} \right) \right) \tag{153}
\]

\[
B^A(w_6^h; Y^h_{n+1}) := \left( w_6^h, V^h_{n+\frac{1}{2}} \right) - \left( w_6^h, \frac{1}{\theta_{n+\frac{1}{2}}^2} \left( 1 + \frac{1}{2} \nu_{\text{loc}}(\rho_{n+\frac{1}{2}} V^h_{n+\frac{1}{2}}) \right) \right) \tag{154}
\]

\[
Y_{n+\frac{1}{2}}^h := \frac{1}{2} (Y^h_n + Y^h_{n+1}), \tag{155}
\]

\[
\rho^h_{n+\frac{1}{2}} := \rho^h(Y^h_{n+\frac{1}{2}}), \tag{156}
\]

\[
u^h_{n+\frac{1}{2}} := \nu^h(Y^h_{n+\frac{1}{2}}), \tag{157}
\]

\[
\theta^h_{n+\frac{1}{2}} := \theta^h(Y^h_{n+\frac{1}{2}}), \tag{158}
\]

\[
\tau^h_{n+\frac{1}{2}} := \frac{1}{\text{Re}} \left( \nabla u_{n+\frac{1}{2}} + \left( \nabla u_{n+\frac{1}{2}} \right)^T - \frac{2}{3} \nabla \cdot u_{n+\frac{1}{2}} \right) \tag{159}
\]
\[
\mathbf{s}_{n+\frac{1}{2}}^h := \frac{1}{\text{We}} \left( \left( \rho_{n+\frac{1}{2}}^h \Delta \rho_{n+\frac{1}{2}}^h + \frac{1}{2} |\nabla \rho_{n+\frac{1}{2}}^h|^2 \right) \mathbf{I} - \nabla \rho_{n+\frac{1}{2}}^h \otimes \nabla \rho_{n+\frac{1}{2}}^h \right),
\]

\[
\mathbf{q}_{n+\frac{1}{2}}^h := -\mathbf{\kappa} \nabla \theta_{n+\frac{1}{2}}^h,
\]

\[
\Pi := \frac{1}{\text{We}} \rho_{n+\frac{1}{2}}^h \nabla \cdot \mathbf{u}_{n+\frac{1}{2}}^h \nabla \rho_{n+\frac{1}{2}}^h,
\]

\[
H_{n+\frac{1}{2}}^h := \frac{8}{27} \rho_{n+\frac{1}{2}}^h \left( \log \left( \frac{\rho_{n+\frac{1}{2}}^h}{1 - \rho_{n+\frac{1}{2}}^h} \right) - \frac{1}{\gamma - 1} \log(\theta_{n+\frac{1}{2}}^h) \right).
\]

### 3.7.2 Preliminary lemmas

We state and prove five lemmas in this section, which will be applied to prove the final results in Section 3.7.3.

**Lemma 3.** The mathematical entropy function \( H(\rho, \theta) \) given by (102) satisfies

\[
\frac{\partial^3 H}{\partial \theta^3} < 0.
\]

**Proof.** Straightforward calculations lead to

\[
\frac{\partial^3 H}{\partial \theta^3} = -\frac{16}{27(\gamma - 1)} \frac{\rho}{\theta^3}.
\]

The dimensionless temperature \( \theta \) is always positive and the heat capacity ratio \( \gamma \) is always greater than 1. Hence,

\[
\frac{\partial^3 H}{\partial \theta^3} < 0.
\]

**Lemma 4.** The local electrochemical potential \( \nu_{\text{loc}}(\rho, \theta) \) given by (100) satisfies

\[
\frac{\partial^3 \nu_{\text{loc}}}{\partial \rho^3} > 0.
\]

**Proof.** Direct calculations yield

\[
\frac{\partial^3 \nu_{\text{loc}}}{\partial \rho^3} = \frac{16\theta}{27} \frac{6\rho^2 - 4\rho + 1}{\rho^3(1 - \rho)^4}.
\]
It is known that $\theta > 0$ and $6\rho^2 - 4\rho + 1 \geq 1/3$. Therefore, one has

$$\frac{\partial^3 \nu_{loc}}{\partial \rho^3} > 0.$$ 

\[ \Box \]

**Lemma 5.** (Perturbed trapezoidal rules) For a function $f \in C^3([m,n])$, where $m, n \in \mathbb{R}$, there exist $\xi_1, \xi_2 \in (m,n)$ such that the following quadrature formulas hold true.

\[
\int_{m}^{n} f(x)dx = \frac{n-m}{2} (f(m) + f(n)) - \frac{(n-m)^3}{12} f''(m) - \frac{(n-m)^4}{24} f'''(\xi_1), \quad (165) \\
\int_{m}^{n} f(x)dx = \frac{n-m}{2} (f(m) + f(n)) - \frac{(n-m)^3}{12} f''(n) + \frac{(n-m)^4}{24} f'''(\xi_2). \quad (166)
\]

The proof for this lemma can be found in the appendix of [?]. There are two other suites of quadrature formulas – the rectangular quadrature rules and the perturbed mid-point rules. Interested readers are referred to [?, ?] for details about these formulas. A common feature of these formulas is that each pair contains opposite signs in the asymptotic residual terms. This allows one to perform a split of the target function and construct a discrete scheme with a controllable residual. This technique will be demonstrated in the following lemma.

**Lemma 6.** Given $[\rho^h_n]$, $[\rho^h_n u^h_n]$, and $[\rho^h_n E(\rho^h_n, u^h_n, \theta^h_n)]$ defined in (142)-(144), the following relation holds for $\xi_1, \xi_2 \in (0,1)$.

\[
\left( \frac{[\rho^h_n]}{\Delta t_n}, \frac{1}{\theta^h_{n+1/2}} \left( \frac{1}{2} \left( \nu_{loc}(\rho^h_n, \theta^h_{n+1/2}) + \nu_{loc}(\rho^h_{n+1}, \theta^h_{n+1/2}) \right) - \frac{[\rho^h_n]^2}{12} \frac{\partial^2 \nu_{loc}(\rho^h_n, \theta^h_{n+1/2})}{\partial \rho^2} \right) \right)_{\Omega} \\
- \left( \frac{[\rho^h_n]}{\Delta t_n}, \frac{[\rho^h_n u^h_n]}{2 \theta^h_{n+1/2}} \right)_{\Omega} + \left( \nabla [\rho^h_n], \frac{1}{2} \left( \nabla \nu_{loc}(\rho^h_n, \theta^h_{n+1/2}) + \nabla \nu_{loc}(\rho^h_{n+1}, \theta^h_{n+1/2}) \right) \right)_{\Omega} + \left( \frac{[\rho^h_n u^h_n]}{\theta^h_{n+1/2}}, \frac{[\rho^h_n]}{\Delta t_n} \right)_{\Omega} \\
- \left( \frac{[\rho^h_n]}{\theta^h_{n+1/2}}, \frac{[\rho^h_n E(\rho^h_n, u^h_n, \theta^h_n)]}{\Delta t_n} \right)_{\Omega} \\
= \int_{\Omega} \frac{H(\rho^h_{n+1}, \theta^h_{n+1}) - H(\rho^h_n, \theta^h_n)}{\Delta t_n} dV_x + \frac{1}{\theta^h_{n+1/2} \Delta t_n} \left( \frac{[\rho^h_n]^4}{24} \frac{\partial^3 \nu_{loc}(\rho^h_n, \theta^h_n)}{\partial \rho^3} \right)_{\Omega} \\
- \left( \frac{1}{\theta^h_{n+1/2} \Delta t_n}, \frac{[\rho^h_n]^4}{24} \frac{\partial^3 H(\rho^h_n, \theta^h_n)}{\partial \rho^3} \right)_{\Omega}. \quad (167)
\]
Proof. Direct calculations can shown that

$$\left( \nabla \left[ \rho_n^h \right] - \frac{1}{\Delta t_n} \nabla \rho_n^h \right)_{\Omega} = \int_\Omega \frac{|\nabla \rho_{n+1}^h|^2 - |\nabla \rho_n^h|^2}{2 \text{We} \, \theta_{n+\frac{1}{2}}^h \Delta t_n} dV_x,$$

and

$$\left( \mathbf{u}_{n+\frac{1}{2}}^h, \left[ \rho_n^h \mathbf{u}_n^h \right] \right) - \left( \left[ \rho_n^h \right], \frac{1}{2} \mathbf{u}_{n+1}^h, \mathbf{u}_n^h \right)_{\Omega} = \int_\Omega \frac{1}{2} \left( \rho_{n+1}^h |\mathbf{u}_{n+1}^h|^2 - \rho_n^h |\mathbf{u}_n^h|^2 \right) dV_x.$$

Making use of the above two relations, one can get

$$\frac{\left[ \rho_n^h \right]}{\Delta t_n} \frac{1}{\theta_{n+\frac{1}{2}}^h} \left( \frac{1}{2} \left( \nu_{\text{loc}}(\rho_n^h, \theta_{n+\frac{1}{2}}^h) + \nu_{\text{loc}}(\rho_{n+1}^h, \theta_{n+\frac{1}{2}}^h) \right) - \frac{\left[ \rho_n^h \right]^2}{12} \frac{\partial^2 \nu_{\text{loc}}}{\partial \rho^2} (\rho_n^h, \theta_{n+\frac{1}{2}}^h) \right)_{\Omega}$$

$$- \left( \frac{\left[ \rho_n^h \right]}{\Delta t_n}, \frac{\mathbf{u}_{n+1}^h \cdot \mathbf{u}_n^h}{2 \theta_{n+\frac{1}{2}}^h} \right)_{\Omega} - \left( \nabla \left[ \rho_n^h \right], \frac{1}{\text{We} \, \theta_{n+\frac{1}{2}}^h} \nabla \rho_n^h \right)_{\Omega} + \left( \mathbf{u}_{n+\frac{1}{2}}^h, \left[ \rho_n^h \mathbf{u}_n^h \right] \right)_{\Omega}$$

$$- \left( \frac{1}{\theta_{n+\frac{1}{2}}^h}, \frac{\rho_n^h \mathbf{E}(\rho_n^h, \mathbf{u}_n^h, \theta_n^h)}{\Delta t_n} \right)_{\Omega}$$

$$= \frac{\left[ \rho_n^h \right]}{\Delta t_n} \frac{1}{\theta_{n+\frac{1}{2}}^h} \left( \frac{1}{2} \left( \nu_{\text{loc}}(\rho_n^h, \theta_{n+\frac{1}{2}}^h) + \nu_{\text{loc}}(\rho_{n+1}^h, \theta_{n+\frac{1}{2}}^h) \right) - \frac{\left[ \rho_n^h \right]^2}{12} \frac{\partial^2 \nu_{\text{loc}}}{\partial \rho^2} (\rho_n^h, \theta_{n+\frac{1}{2}}^h) \right)_{\Omega}$$

$$- \left( \frac{1}{\theta_{n+\frac{1}{2}}^h \Delta t_n}, \left( \rho \nabla_{\text{loc}}(\rho_n^h, \theta_{n+\frac{1}{2}}^h) - \left( \rho \nabla_{\text{loc}}(\rho_{n+1}^h, \theta_{n+\frac{1}{2}}^h) \right) \right. \right.$$  

$$- \left( \rho \nabla_{\text{loc}}(\rho_{n+1}^h, \theta_{n+\frac{1}{2}}^h) - \theta_{n+\frac{1}{2}} \left( H(\rho_{n+1}^h, \theta_{n+1}^h) - H(\rho_n^h, \theta_n^h) \right) \right.$$  

$$- \left( 2 H(\rho_{n+\frac{1}{2}}^h, \theta_{n+\frac{1}{2}}^h) + H(\rho_{n+\frac{1}{2}}^h, \theta_n^h) \right) + \left[ \frac{\theta_{n+\frac{1}{2}}^h}{12} \frac{\partial^2 \nabla_{\text{loc}}(\rho_{n+\frac{1}{2}}^h, \theta_{n+\frac{1}{2}}^h) \right)_{\Omega}}{12} \frac{\partial^2 \nu_{\text{loc}}}{\partial \rho^2} (\rho_n^h, \theta_{n+\frac{1}{2}}^h) \right)_{\Omega} \right) \right). \quad (168)$$

Applying the perturbed trapezoidal rule (165) to

$$\nu_{\text{loc}} = \frac{\partial (\rho \nabla_{\text{loc}} \rho_n) \rho_n}{\partial \rho},$$

one can get

$$(\rho \nabla_{\text{loc}}(\rho_{n+1}^h, \theta_{n+\frac{1}{2}}^h)) - (\rho \nabla_{\text{loc}}(\rho_n^h, \theta_{n+\frac{1}{2}}^h)) = \int_{\rho_n^h}^{\rho_{n+1}^h} \frac{\partial (\rho \nabla_{\text{loc}} \rho_n) \rho_n}{\partial \rho} \, d\rho = \int_{\rho_n^h}^{\rho_{n+1}^h} \nu_{\text{loc}} \, d\rho$$

$$= \frac{\left[ \rho_n^h \right]}{2} \left( \nu_{\text{loc}}(\rho_n^h, \theta_{n+\frac{1}{2}}^h) + \nu_{\text{loc}}(\rho_{n+1}^h, \theta_{n+\frac{1}{2}}^h) \right) - \frac{\left[ \rho_n^h \right]^3}{12} \frac{\partial^2 \nu_{\text{loc}}}{\partial \rho^2} (\rho_n^h, \theta_{n+\frac{1}{2}}^h) - \frac{\left[ \rho_n^h \right]^4}{24} \frac{\partial^3 \nu_{\text{loc}}}{\partial \rho^3} (\rho_{n+\frac{1}{2}}^h, \theta_{n+\frac{1}{2}}^h),$$

52
for $\xi_1 \in (0, 1)$. Consequently, the relation (168) can be rewritten as

$$
\left( \frac{[\rho^h_n]}{\Delta t_n}, \frac{1}{\theta^h_{n+\frac{1}{2}}}, \frac{1}{2^2} \left( \nu_{\text{loc}}(\rho^h_n, \theta^h_{n+\frac{1}{2}}) + \nu_{\text{loc}}(\rho^h_{n+1}, \theta^h_{n+\frac{1}{2}}) \right) - \frac{[\rho^h_n]^2}{12} \frac{\partial^2 \nu_{\text{loc}}(\rho^h_n, \theta^h_{n+\frac{1}{2}})}{\partial \rho^2} \right) \Omega
$$

$$
- \left( \frac{[\rho^h_n]}{\Delta t_n}, \frac{u^h_{n+1} \cdot u^h_n}{2 \theta^h_{n+\frac{1}{2}}} \right) \Omega
+ \left( \frac{\nabla [\rho^h_n]}{\Delta t_n}, \frac{1}{\theta^h_{n+\frac{1}{2}}} \nabla \rho^h_{n+\frac{1}{2}} \right) \Omega
+ \left( \frac{u^h_{n+\frac{1}{2}}}{\theta^h_{n+\frac{1}{2}}}, \frac{[\rho^h_n] u^h_n}{\Delta t_n} \right) \Omega
$$

$$
\Omega
- \left( \frac{1}{\theta^h_{n+\frac{1}{2}}}, \frac{\rho^h_n E(\rho^h_n, u^h_n, \theta^h_n)}{\Delta t_n} \right) \Omega
$$

$$
= \left( \frac{1}{\theta^h_{n+\frac{1}{2}}}, \frac{[\rho^h_n]^4}{24} \frac{\partial^3 \nu_{\text{loc}}(\rho^h_n, \theta^h_{n+\frac{1}{2}})}{\partial \rho^3} \right) \Omega
- \left( \frac{1}{\theta^h_{n+\frac{1}{2}}}, \frac{[\rho^h_n]^2}{12} \frac{\partial^2 \nu_{\text{loc}}(\rho^h_n, \theta^h_{n+\frac{1}{2}})}{\partial \rho^2} \right) \Omega
$$

$$
= \left( 1, \frac{H(\rho^h_{n+1}, \theta^h_{n+1}) - H(\rho^h_n, \theta^h_n)}{\partial \theta} \right) \Omega
$$

$$
= \frac{\theta^h_{n+1}}{2} \left( H(\rho^h_{n+\frac{1}{2}}, \theta^h_{n+1}) + H(\rho^h_{n+\frac{1}{2}}, \theta^h_n) \right) + \frac{\theta^h_{n+1}}{12} \frac{\partial^2 H}{\partial \theta^2}(\rho^h_{n+\frac{1}{2}}, \theta^h_n) + \frac{\theta^h_{n+1}}{24} \frac{\partial^3 H}{\partial \theta^3}(\rho^h_{n+\frac{1}{2}}, \theta^h_n, \xi_2),
$$

for $\xi_2 \in (0, 1)$. Using the above relation, relation (169) can be further rewritten as

$$
H = \frac{\partial (\rho \Psi_{\text{loc}})}{\partial \theta}
$$

leads to

$$
(\rho \Psi_{\text{loc}})(\rho^h_{n+\frac{1}{2}}, \theta^h_{n+1}) - (\rho \Psi_{\text{loc}})(\rho^h_{n+\frac{1}{2}}, \theta^h_n) = \int_{\theta^h_n}^{\theta^h_{n+1}} \frac{\partial (\rho \Psi_{\text{loc}})}{\partial \theta} d\theta = \int_{\theta^h_n}^{\theta^h_{n+1}} H d\theta
$$

$$
= \frac{\theta^h_{n+1}}{2} \left( H(\rho^h_{n+\frac{1}{2}}, \theta^h_{n+1}) + H(\rho^h_{n+\frac{1}{2}}, \theta^h_n) \right) - \frac{\theta^h_{n+1}^3}{12} \frac{\partial^2 H}{\partial \theta^2}(\rho^h_{n+\frac{1}{2}}, \theta^h_n) + \frac{\theta^h_{n+1}^3}{24} \frac{\partial^3 H}{\partial \theta^3}(\rho^h_{n+\frac{1}{2}}, \theta^h_n, \xi_2),
$$

for $\xi_2 \in (0, 1)$. Using the above relation, relation (169) can be further rewritten as

$$
\left( \frac{[\rho^h_n]}{\Delta t_n}, \frac{1}{\theta^h_{n+\frac{1}{2}}}, \frac{1}{2^2} \left( \nu_{\text{loc}}(\rho^h_n, \theta^h_{n+\frac{1}{2}}) + \nu_{\text{loc}}(\rho^h_{n+1}, \theta^h_{n+\frac{1}{2}}) \right) - \frac{[\rho^h_n]^2}{12} \frac{\partial^2 \nu_{\text{loc}}(\rho^h_n, \theta^h_{n+\frac{1}{2}})}{\partial \rho^2} \right) \Omega
$$

$$
- \left( \frac{[\rho^h_n]}{\Delta t_n}, \frac{u^h_{n+1} \cdot u^h_n}{2 \theta^h_{n+\frac{1}{2}}} \right) \Omega
+ \left( \frac{\nabla [\rho^h_n]}{\Delta t_n}, \frac{1}{\theta^h_{n+\frac{1}{2}}} \nabla \rho^h_{n+\frac{1}{2}} \right) \Omega
+ \left( \frac{u^h_{n+\frac{1}{2}}}{\theta^h_{n+\frac{1}{2}}}, \frac{[\rho^h_n] u^h_n}{\Delta t_n} \right) \Omega
$$

$$
\Omega
- \left( \frac{1}{\theta^h_{n+\frac{1}{2}}}, \frac{\rho^h_n E(\rho^h_n, u^h_n, \theta^h_n)}{\Delta t_n} \right) \Omega
$$

$$
= \left( \frac{1}{\theta^h_{n+\frac{1}{2}}}, \frac{[\rho^h_n]^4}{24} \frac{\partial^3 \nu_{\text{loc}}(\rho^h_n, \theta^h_{n+\frac{1}{2}})}{\partial \rho^3} \right) \Omega
+ \left( \frac{1}{\Delta t_n}, (H(\rho^h_{n+1}, \theta^h_{n+1}) - H(\rho^h_n, \theta^h_n)) \right) \Omega
$$

53
\[-\left(\frac{1}{\theta_{n+\frac{1}{2}}^h}\Delta t_n, \left[\rho_n^h\right]^4 \frac{\partial^3 H}{\partial \rho^3} (\rho_{n+\frac{1}{2}}^h, \theta_{n+\xi_2}^h)\right)_{\Omega} \]

\[= \int_{\Omega} \frac{H(\rho_{n+1}^h, \theta_{n+1}^h) - H(\rho_n^h, \theta_n^h)}{\Delta t_n} dV + \left(\frac{1}{\theta_{n+\frac{1}{2}}^h}\Delta t_n, \left[\rho_n^h\right]^4 \frac{\partial^3 \nu_{\text{loc}}}{\partial \rho^3} (\rho_{n+\xi_1}^h, \theta_{n+\frac{1}{2}}^h)\right)_{\Omega} \]

\[-\left(\frac{1}{\theta_{n+\frac{1}{2}}^h}\Delta t_n, \left[\rho_n^h\right]^4 \frac{\partial^3 H}{\partial \theta^3} (\rho_{n+\frac{1}{2}}^h, \theta_{n+\xi_2}^h)\right)_{\Omega}.\]

This completes the proof of Lemma 6. \(\square\)

**Remark 12.** Based on Lemmas 3 and 4, one can show that the last two terms in (167) satisfy

\[\left(\frac{1}{\theta_{n+\frac{1}{2}}^h}\Delta t_n, \left[\rho_n^h\right]^4 \frac{\partial^3 \nu_{\text{loc}}}{\partial \rho^3} (\rho_{n+\xi_1}^h, \theta_{n+\frac{1}{2}}^h)\right)_{\Omega} \geq 0,\]

\[\left(\frac{1}{\theta_{n+\frac{1}{2}}^h}\Delta t_n, \left[\rho_n^h\right]^4 \frac{\partial^3 H}{\partial \theta^3} (\rho_{n+\frac{1}{2}}^h, \theta_{n+\xi_2}^h)\right)_{\Omega} \leq 0.\]

The two terms represent the numerical dissipation introduced by the approximation of time derivatives.

**Remark 13.** In the proof of Lemma 6, it is clear that the novel jump operator (144) is designed based on the perturbed trapezoidal formulas (165) and (166). It should be pointed out that one may construct different discrete jump operators for \(\partial (\rho E)/\partial t\) by using the perturbed mid-point rules or the rectangular quadrature rules proposed in [?]. The resulting schemes can be shown to guarantee the dissipation property, but the amount of numerical dissipation will be slightly different.

**Lemma 7.** Replacing \(\rho_n^h, \mathbf{u}_n^h, \) and \(\theta_n^h\) in the definition (144) with corresponding time continuous functions \(\rho^h(t_n), \mathbf{u}^h(t_n), \) and \(\theta^h(t_n)\) and assuming sufficient smoothness in the time direction, one has

\[\left[\rho^h(t_n)E(\rho^h(t_n), \mathbf{u}^h(t_n), \theta^h(t_n))\right]\]

\[= \left(\rho^h(t_{n+1})E(\rho^h(t_{n+1}), \mathbf{u}^h(t_{n+1}), \theta^h(t_{n+1})) - \rho^h(t_n)E(\rho^h(t_n), \mathbf{u}^h(t_n), \theta^h(t_n))\right) + O(\Delta t^3).\]

**Proof.** Recalling the relations (145)-(149), we only need to analyze the non-classical jump operators (146) and (147). We consider the jump operator (146) first. Taylor expansions
lead to

\[
(r\Psi_{\text{loc}})(r^h(t_{n+1}), \theta^h(t_{n+1})) = (r\Psi_{\text{loc}})(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \\
+ \frac{\partial(r\Psi_{\text{loc}})}{\partial r}(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \left(r^h(t_{n+1}) - r^h(t_{n+\frac{1}{2}})\right) \\
+ \frac{\partial(r\Psi_{\text{loc}})}{\partial \theta}(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \left(\theta^h(t_{n+1}) - \theta^h(t_{n+\frac{1}{2}})\right) \\
+ \frac{1}{2} \frac{\partial^2(r\Psi_{\text{loc}})}{\partial r^2}(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \left(r^h(t_{n+1}) - r^h(t_{n+\frac{1}{2}})\right)^2 \\
+ \frac{1}{2} \frac{\partial^2(r\Psi_{\text{loc}})}{\partial \theta^2}(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \left(\theta^h(t_{n+1}) - \theta^h(t_{n+\frac{1}{2}})\right)^2 \\
+ \frac{\partial^2(r\Psi_{\text{loc}})}{\partial r \partial \theta}(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \left(r^h(t_{n+1}) - r^h(t_{n+\frac{1}{2}})\right) \left(\theta^h(t_{n+1}) - \theta^h(t_{n+\frac{1}{2}})\right) \\
+ O(\Delta t^3),
\]

(170)

\[
(r\Psi_{\text{loc}})(r^h(t_n), \theta^h(t_n)) = (r\Psi_{\text{loc}})(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \\
+ \frac{\partial(r\Psi_{\text{loc}})}{\partial r}(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \left(r^h(t_{n}) - r^h(t_{n+\frac{1}{2}})\right) \\
+ \frac{\partial(r\Psi_{\text{loc}})}{\partial \theta}(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \left(\theta^h(t_{n}) - \theta^h(t_{n+\frac{1}{2}})\right) \\
+ \frac{1}{2} \frac{\partial^2(r\Psi_{\text{loc}})}{\partial r^2}(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \left(r^h(t_{n}) - r^h(t_{n+\frac{1}{2}})\right)^2 \\
+ \frac{1}{2} \frac{\partial^2(r\Psi_{\text{loc}})}{\partial \theta^2}(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \left(\theta^h(t_{n}) - \theta^h(t_{n+\frac{1}{2}})\right)^2 \\
+ \frac{\partial^2(r\Psi_{\text{loc}})}{\partial r \partial \theta}(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \left(r^h(t_{n}) - r^h(t_{n+\frac{1}{2}})\right) \left(\theta^h(t_{n}) - \theta^h(t_{n+\frac{1}{2}})\right) \\
+ O(\Delta t^3),
\]

(171)

\[
(r\Psi_{\text{loc}})(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+1})) = (r\Psi_{\text{loc}})(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \\
+ \frac{\partial(r\Psi_{\text{loc}})}{\partial \theta}(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \left(\theta^h(t_{n+1}) - \theta^h(t_{n+\frac{1}{2}})\right) \\
+ \frac{1}{2} \frac{\partial^2(r\Psi_{\text{loc}})}{\partial r^2}(r^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) \left(\theta^h(t_{n+1}) - \theta^h(t_{n+\frac{1}{2}})\right)^2 \\
+ O(\Delta t^3),
\]

(172)
Combining the above Taylor expansions leads to

\[ (\rho \Psi_{\text{loc}})(\rho^h(t_{n+1}), \theta^h(t_{n+1})) = (\rho \Psi_{\text{loc}})(\rho^h(t_{n+1}), \theta^h(t_{n+1})) + \frac{\partial (\rho \Psi_{\text{loc}})}{\partial \rho} (\rho^h(t_{n+1}), \theta^h(t_{n+1})) (\rho^h(t_{n+1}) - \rho^h(t_{n+\frac{1}{2}})) + \frac{1}{2} \frac{\partial^2 (\rho \Psi_{\text{loc}})}{\partial \rho^2} (\rho^h(t_{n+1}), \theta^h(t_{n+1})) (\rho^h(t_{n+1}) - \rho^h(t_{n+\frac{1}{2}}))^2 + \mathcal{O}(\Delta t^3), \]  

(173)

\[ (\rho \Psi_{\text{loc}})(\rho^h(t_n), \theta^h(t_{n+\frac{3}{4}})) = (\rho \Psi_{\text{loc}})(\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) + \frac{\partial (\rho \Psi_{\text{loc}})}{\partial \rho} (\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) (\rho^h(t_n) - \rho^h(t_{n+\frac{1}{2}})) + \frac{1}{2} \frac{\partial^2 (\rho \Psi_{\text{loc}})}{\partial \rho^2} (\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) (\rho^h(t_n) - \rho^h(t_{n+\frac{1}{2}}))^2 + \mathcal{O}(\Delta t^3). \]  

(174)

Combining the above Taylor expansions leads to

\[ \left( (\rho \Psi_{\text{loc}})(\rho^h(t_{n+1}), \theta^h(t_{n+1})) - (\rho \Psi_{\text{loc}})(\rho^h(t_n), \theta^h(t_n)) \right) - \left( (\rho \Psi_{\text{loc}})(\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) - (\rho \Psi_{\text{loc}})(\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_{n})) \right) + (\rho \Psi_{\text{loc}})(\rho^h(t_{n+1}), \theta^h(t_{n+\frac{1}{2}})) - (\rho \Psi_{\text{loc}})(\rho^h(t_{n}), \theta^h(t_{n+\frac{1}{2}}))) = \mathcal{O}(\Delta t^3). \]

Next, we analyze the term (147).

\[ \left( \theta^h(t_{n+1}) H(\rho^h(t_{n+1}), \theta^h(t_{n+1})) - \theta^h(t_n) H(\rho^h(t_n), \theta^h(t_n)) \right) \]

\[ - \left( \theta^h(t_{n+\frac{1}{2}}) \left( H(\rho^h(t_{n+1}), \theta^h(t_{n+1})) - H(\rho^h(t_n), \theta^h(t_n)) \right) \right) \]

\[ + \frac{\theta^h(t_{n+1}) - \theta^h(t_n)}{2} \left( H(\rho^h(t_{n+\frac{3}{4}}), \theta^h(t_{n+1})) + H(\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_{n})) \right) \]

\[ = \frac{\theta^h(t_{n+1}) - \theta^h(t_n)}{2} \left( H(\rho^h(t_{n+\frac{3}{4}}), \theta^h(t_{n+1})) + H(\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_{n})) \right) \]

\[ - H(\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+1})) - H(\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_{n})) + \mathcal{O}(\Delta t^3) \]

\[ = \frac{(\theta^h(t_{n+1}) - \theta^h(t_n))}{2} \left( \frac{\partial H}{\partial \rho} (\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+1})) (\rho^h(t_{n+1}) - \rho^h(t_{n+\frac{1}{2}})) \right) \]

56
\[ - \frac{\partial H}{\partial \rho} (\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_n)) \left( \rho^h(t_n) - \rho^h(t_{n+\frac{1}{2}}) \right) + O(\Delta t^3) \]

= \mathcal{O}(\Delta t^3). \tag{176} 

According to (170) and (176), it can be concluded that

\[ \left[ \rho^h(t_n) \nabla (\rho^h(t_n), u^h(t_n), \theta^h(t_n)) \right] \]

\[ - \left( \rho^h(t_{n+1}) \nabla (\rho^h(t_{n+1}), u^h(t_{n+1}), \theta^h(t_{n+1})) - \rho^h(t_n) \nabla (\rho^h(t_n), u^h(t_n), \theta^h(t_n)) \right) \]

\[ = \mathcal{O}(\Delta t^3) + \frac{(\theta^h(t_{n+1}) - \theta^h(t_n))^3 \partial^2 H}{12} (\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+1})) \]

\[ = \mathcal{O}(\Delta t^3). \]

This completes the proof of the lemma. \[\square\]

This lemma reveals that the jump operator we defined in (144) is in fact a third-order perturbation to the classical energy jump. Using this fact, we can prove the second-order accuracy of our numerical scheme.

#### 3.7.3 Numerical dissipation and accuracy

With the above five lemmas, we are ready to state and prove the main results of the fully discrete scheme (150)-(153).

**Theorem 6.** The solutions of the fully discrete scheme (150)-(153) satisfy

\[
\int_{\Omega} \left( \frac{H(\rho^h_{n+1}, \theta^h_{n+1}) - H(\rho^h_n, \theta^h_n)}{\Delta t_n} + \nabla \cdot \left( H(\rho^h_{n+\frac{1}{2}}, \theta^h_{n+\frac{1}{2}}) u^h_{n+\frac{1}{2}} \right) - \nabla \cdot \left( \frac{q^h_{n+\frac{1}{2}}}{\theta^h_{n+\frac{1}{2}}} \right) \right) dV_x \\
+ \frac{\rho^h_{n+\frac{1}{2}} \theta^h_{n+\frac{1}{2}}}{\theta^h_{n+\frac{1}{2}}^2} \right) dV_x \\
- \int_{\Omega} \frac{1}{\theta^h_{n+\frac{1}{2}}} \cdot \nabla u^h_{n+\frac{1}{2}} dV_x - \int_{\Omega} \frac{\nabla \theta^h_{n+\frac{1}{2}} \cdot \kappa \nabla \theta^h_{n+\frac{1}{2}}}{\left( \theta^h_{n+\frac{1}{2}} \right)^2} dV_x \\
- \int_{\Omega} \frac{1}{\theta^h_{n+\frac{1}{2}}} \Delta t_n \left[ \phi^h_n \right]^4 \frac{\partial^3 \nu_{loc}}{\partial \rho^3} (\rho^h_{n+\frac{1}{2}}, \theta^h_{n+\frac{1}{2}}) dV_x + \int_{\Omega} \frac{1}{\theta^h_{n+\frac{1}{2}}} \Delta t_n \left[ \phi^h_n \right]^4 \frac{\partial^3 H}{\partial \rho^3} (\rho^h_{n+\frac{1}{2}}, \theta^h_{n+\frac{1}{2}}, \xi) dV_x \\
\leq 0. \tag{177} 
\]

**Proof.** Taking \( w^h_1 = V^h_{n+\frac{1}{2}} \) in (150), \( w^h = u^h_{n+\frac{1}{2}}/\rho^h_{n+\frac{1}{2}} \) in (151), \( w^h_5 = -1/\rho^h_{n+\frac{1}{2}} \) in (152), \( w^h_6 = [\phi^h_n]/\Delta t_n \) in (153), combing the three equations, and following the proof of Theorem
According to Lemma 6, the above relation can be reorganized as

\[
\int_{\Omega} \left( \frac{H(\rho_{n+1}^h, \theta_{n+1}^h) - H(\rho_n^h, \theta_n^h)}{\Delta t_n} + \nabla \cdot (H(\rho_{n+1}^h, \theta_{n+1}^h)u_{n+1}^h) - \nabla \cdot \left( \frac{\rho_{n+1}^h}{\theta_{n+1}^h} \right) \right) dV_x
\]

\[
= -\int_{\Omega} \frac{1}{\theta_{n+1}^h} \tau_{n+1}^h : \nabla u_{n+1}^h dV_x - \int_{\Omega} \frac{\nabla \theta_{n+1}^h \cdot \kappa \nabla \theta_{n+1}^h}{(\theta_{n+1}^h)^2} dV_x
\]

\[
- \int_{\Omega} \frac{1}{\theta_{n+1}^h} \frac{1}{\Delta t_n} \left[ \frac{\rho_n^h}{\theta_{n+1}^h} \right]^4 \frac{\partial^3 \omega_{loc}(\rho_{n+1}^h, \theta_{n+1}^h)}{\partial \rho^3} dV_x + \int_{\Omega} \frac{1}{\theta_{n+1}^h} \frac{1}{\Delta t_n} \frac{\left[ \theta_n^h \right]^4}{24} \frac{\partial^3 H(\rho_{n+1}^h, \theta_{n+1}^h)}{\partial \theta^3} dV_x
\]

\[
\leq 0.
\]

The last inequality is due to Lemmas 3 and 4.

**Remark 14.** This theorem implies that the fully discrete solutions respect the second law of thermodynamics. The amount of dissipation in (177) consists of two parts: the physical dissipation and the numerical dissipation. From our analysis, the numerical dissipation purely comes from the temporal scheme, and it will vanish if the time step approaches zero.

**Theorem 7.** The local truncation error in time \(\tau(t)\) can be bounded by \(|\tau(t)| \leq K\Delta t_n^2\) for all \(t_n \in [0, T]\), where \(K\) is a constant independent of \(\Delta t_n\).
Proof. We start by considering the mid-point rule applied to the semi-discrete formulation (136)-(139). The fully discrete scheme reads

\[
B^M_{mid}(w^h_1; Y^h_{n+1}) := (w^h_1, \frac{\rho^h}{\Delta t_n} \Omega) - \left( \nabla w^h_1, \rho^h_{n+\frac{1}{2}} u^h_{n+\frac{1}{2}} \Omega \right) = 0,
\]

\[
B^U_{mid}(w^h; Y^h_{n+1}) := (w^h, \frac{[\rho^h u^h]}{\Delta t_n} \Omega) - \left( \nabla w^h, \rho^h_{n+\frac{1}{2}} u^h_{n+\frac{1}{2}} \otimes u^h_{n+\frac{1}{2}} \Omega \right)
\]

\[
- \left( \nabla \cdot w^h, \rho^h_{n+\frac{1}{2}} V^h_{mid} \theta^h_{n+\frac{1}{2}} + \frac{1}{2} \rho^h_{n+\frac{1}{2}} |u^h_{n+\frac{1}{2}}|^2 + \frac{1}{\text{We}} \rho^h_{n+\frac{1}{2}} \theta^h_{n+\frac{1}{2}} \nabla \cdot \left( \frac{\nabla \rho^h_{n+\frac{1}{2}}}{\theta^h_{n+\frac{1}{2}}} \right) \Omega \right)
\]

\[
- \left( w^h, \left( V^h_{mid} \theta^h_{n+\frac{1}{2}} + \frac{|u^h_{n+\frac{1}{2}}|^2}{2} \right) + \frac{1}{\text{We}} \rho^h_{n+\frac{1}{2}} \nabla \cdot \left( \frac{\nabla \rho^h_{n+\frac{1}{2}}}{\theta^h_{n+\frac{1}{2}}} \right) \right) \nabla \rho^h_{n+\frac{1}{2}} \Omega
\]

\[
- \left( w^h, \nabla \theta^h_{n+\frac{1}{2}} \Omega \right) + \left( \nabla w^h, \tau^h_{n+\frac{1}{2}} \Omega \right) + \left( \nabla w^h, \phi^h_{n+\frac{1}{2}} \Omega \right) - \left( w^h, \rho^h_{n+\frac{1}{2}} b \right) \Omega = 0,
\]

\[
B^E_{mid}(w^h_5; Y^h_{n+1}) := \left( w^h_5, \frac{\rho^h_{n+1} E(r^h_{n+1}, u^h_{n+1}, \theta^h_{n+1}) - \rho^h_5 E(r^h_5, u^h_5, \theta^h_5)}{\Delta t_n} \right) \Omega
\]

\[
- \left( \nabla w^h_5, \left( \rho^h_5 V^h_{mid} \theta^h_{n+\frac{1}{2}} - \theta^h_{n+\frac{1}{2}} \nabla \theta^h_{n+\frac{1}{2}} - \frac{1}{2} \rho^h_5 \nabla |u^h_{n+\frac{1}{2}}|^2 + \rho^h_5 |u^h_{n+\frac{1}{2}}|^2 \right)
\]

\[
+ \frac{1}{\text{We}} \rho^h_{n+\frac{1}{2}} \theta^h_{n+\frac{1}{2}} \nabla \cdot \left( \frac{\nabla \rho^h_{n+\frac{1}{2}}}{\theta^h_{n+\frac{1}{2}}} \right) u^h_{n+\frac{1}{2}} \Omega + \left( \nabla w^h_5, \tau^h_{n+\frac{1}{2}} u^h_{n+\frac{1}{2}} \Omega \right) + \left( \nabla w^h_5, \phi^h_{n+\frac{1}{2}} u^h_{n+\frac{1}{2}} \Omega \right)
\]

\[
- \left( \nabla w^h_5, \phi^h_{n+\frac{1}{2}} \Omega \right) - \left( \nabla w^h_5, \phi^h_{n+\frac{1}{2}} \Omega \right) - \left( w^h_5, \rho^h_{n+\frac{1}{2}} b \cdot u^h_{n+\frac{1}{2}} \Omega \right) - \left( w^h_5, \rho^h_{n+\frac{1}{2}} r \Omega \right) = 0,
\]

\[
B^A_{mid}(w^h_6; Y^h_{n+1}) := (w^h_6, V^h_{mid}) \Omega - \left( w^h_6, \frac{1}{\theta^h_{n+\frac{1}{2}}} \left( v_{loc}(\rho^h_{n+\frac{1}{2}}, \theta^h_{n+\frac{1}{2}} - \frac{|u^h_{n+\frac{1}{2}}|^2}{2} \right) \right) \Omega
\]

\[
- \left( \nabla w^h_6, \frac{1}{\text{We}} \nabla \rho^h_{n+\frac{1}{2}} \Omega \right) = 0.
\]

The local truncation errors associated with the mid-point rule can be obtained by replacing the time discrete solutions with the corresponding exact time continuous solution:

\[
B^M_{mid}(w^h_1; Y^h(t)) = (w^h_1, \Theta^m_{\rho} \Omega),
\]

\[
B^U_{mid}(w^h; Y^h(t)) = (w^h, \Theta^m_{u} \Omega),
\]

\[
B^E_{mid}(w^h_5; Y^h(t)) = (w^h_5, \Theta^m_{E} \Omega),
\]

\[
B^A_{mid}(w^h_6; Y^h(t)) = (w^h_6, \Theta^m_{A} \Omega).
\]
Assuming sufficient smoothness for the time continuous solutions, one can show that

\[
\Theta_{\rho}^{mid} = \mathcal{O}(\Delta t_n^2), \quad \Theta_{u}^{mid} = \mathcal{O}(\Delta t_n^2) 1,
\]

\[
\Theta_{E}^{mid} = \mathcal{O}(\Delta t_n^2), \quad \Theta_{A}^{mid} = \mathcal{O}(\Delta t_n^2).
\]

Now replacing the time discrete solutions with corresponding time continuous solutions in the fully discrete formulation (150)-(153):

\[
B^M(w^h_1; Y^h(t)) = (w^h_1, \Theta_{\rho})_{\Omega}, \\
B^U(w^h; Y^h(t)) = (w^h_1, \Theta_{u})_{\Omega}, \\
B^E(w^h_1; Y^h(t)) = (w^h_1, \Theta_{E})_{\Omega}, \\
B^A(w^h_1; Y^h(t)) = (w^h_1, \Theta_{A})_{\Omega}.
\]

Taylor expansions lead to

\[
\frac{1}{2} \left( \nu_{\text{loc}}(\rho^h(t_n), \theta^h(t_{n+\frac{1}{2}})) + \nu_{\text{loc}}(\rho^h(t_{n+1}), \theta^h(t_{n+\frac{1}{2}})) \right) = \nu_{\text{loc}}(\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}})) + \mathcal{O}(\Delta t_n^2),
\]

\[
\frac{[\rho^h(t_n)]^2}{12} \frac{\partial^2 \nu_{\text{loc}}(\rho^h(t_{n+\frac{1}{2}}), \theta^h(t_{n+\frac{1}{2}}))}{\partial \rho^2} = \mathcal{O}(\Delta t_n^2),
\]

\[
2|u^h(t_{n+\frac{1}{2}})|^2 - \frac{1}{2}(|u^h(t_n)|^2 + |u^h(t_{n+1})|^2) = |u^h(t_{n+\frac{1}{2}})|^2 + \mathcal{O}(\Delta t_n^2).
\]

Due to Lemma 7, one has

\[
\frac{\rho^h_{n+1} E(\rho^h_{n+1}, u^h_{n+1}, \theta^h_{n+1}) - \rho^h_n E(\rho^h_n, u^h_n, \theta^h_n)}{\Delta t_n} - \left[ \frac{\rho^h_n E(\rho^h_n, u^h_n, \theta^h_n)}{\Delta t_n} \right] = \mathcal{O}(\Delta t_n^2).
\]

Combing the above results gives us

\[
(w^h_1, \Theta_{\rho})_{\Omega} = (w^h_1, \Theta_{\rho}^{mid})_{\Omega} + \mathcal{O}(\Delta t_n^2) = \mathcal{O}(\Delta t_n^2),
\]

\[
(w^h_1, \Theta_{u})_{\Omega} = (w^h_1, \Theta_{u}^{mid})_{\Omega} + \mathcal{O}(\Delta t_n^2) 1 = \mathcal{O}(\Delta t_n^2) 1,
\]

\[
(w^h_1, \Theta_{E})_{\Omega} = (w^h_1, \Theta_{E}^{mid})_{\Omega} + \mathcal{O}(\Delta t_n) = \mathcal{O}(\Delta t_n^2),
\]

\[
(w^h_1, \Theta_{A})_{\Omega} = (w^h_1, \Theta_{A}^{mid})_{\Omega} + \mathcal{O}(\Delta t_n^2) = \mathcal{O}(\Delta t_n^2).
\]

This completes the proof. \(\square\)

**Remark 15.** According to the proof of Theorem 7, we can see that the fully discrete scheme (150)-(153) is a second-order perturbation of the mid-point scheme. This perturbation guarantees the entropy dissipation (177).
4 Benchmark problems

In this section, we use a suite of benchmark problems to verify the theoretical estimates we made in Section 3.

4.1 Manufactured solutions

As a first example, we construct a set of one-dimensional manufactured solutions for the Navier-Stokes-Korteweg equations to corroborate the time accuracy estimate given in Theorem 7. The computations are restricted to \( \Omega = (0,1) \); the exact density, velocity, and temperature for this problem are chosen as

\[
\begin{align*}
\rho(x,t) &= 0.5 + 0.1 \sin(\pi t) \cos(2\pi x), \\
u(x,t) &= \sin(\pi t) \cos(2\pi x), \\
\theta(x,t) &= 0.85 + 0.1 \sin(\pi t) \sin(4\pi x).
\end{align*}
\]
The forcing terms for the balance equations are obtained by substituting the above exact solutions into the original strong problem (86)-(88). The $Y$ variables can be obtained as

$$Y_1 = \rho = 0.5 + 0.1 \sin(\pi t) \cos(2\pi x),$$

$$Y_2 = \frac{u}{\theta} = \frac{\sin(\pi t) \cos(2\pi x)}{0.85 + 0.1 \sin(\pi t) \sin(4\pi x)},$$

$$Y_3 = -\frac{1}{\theta} = -\frac{1}{0.85 + 0.1 \sin(\pi t) \sin(4\pi x)}.$$

The dimensionless numbers for this verification problem are fixed to be $\text{Re} = 1.0$, $\text{We} = 1.0$, and $\gamma = 1.333$. The dimensionless thermal conductivity is chosen as $\kappa = 1.0$. Periodic boundary conditions are enforced for all variables. The problem is computed with spatial mesh size $\Delta x = 1.0 \times 10^{-3}$ for polynomial degrees $p = 2$ and 3. The time step sizes are taken as $1.0 \times 10^{-1}$, $5.0 \times 10^{-2}$, $1.0 \times 10^{-2}$, $5.0 \times 10^{-3}$, and $5.0 \times 10^{-4}$. In Table 1, the errors in $L^2$-norm for the quadratic NURBS solutions and the errors in $H^1$ semi-norm for the cubic NURBS solutions are summarized. It can be observed that the temporal errors converge like $O(\Delta t^2)$ in both cases. This immediately confirms the time accuracy estimate given in Theorem 7.

4.2 Coalescence of two vapor bubbles

In this example, we consider a one-dimensional problem without external sources (i.e., $b = 0$ and $r = 0$) to verify the entropy dissipation estimate given in Theorem 6. The computational domain is set to be $\Omega = (0, 1)$. The initial conditions consist of two static vapor bubbles with centers at points $C_1 = 0.39$ and $C_2 = 0.61$. The radii of the bubbles are set to be $R_1 = R_2 = 0.1$. The initial density is given by the following hyperbolic tangent function.

$$\rho_0(x) = 0.1 + 0.25 \left[ \tanh \left( \frac{d_1(x) - R_1}{2 \sqrt{\text{We}}} \right) + \tanh \left( \frac{d_2(x) - R_2}{2 \sqrt{\text{We}}} \right) \right],$$

$$d_i(x) = |x - C_i|, \quad \text{for } i = 1, 2.$$

The initial velocity is zero and the initial temperature is $\theta_0 = 0.95$. Periodic boundary conditions are applied for all variables. The dimensionless numbers are taken as $\text{Re} = 4.0 \times 10^2$, $\text{We} = 1.6 \times 10^5$, and $\gamma = 1.333$; the dimensionless thermal conductivity is taken as $\kappa = 1.0$. The spatial mesh consists of $10^4$ quadratic NURBS functions. The problem is integrated up to $T = 10.0$ with time step sizes $\Delta t = 1.0 \times 10^{-2}$, $5.0 \times 10^{-3}$, $2.0 \times 10^{-3}$, and $1.0 \times 10^{-5}$.

The two vapor bubbles will merge together to minimize the surface energy. At the
Figure 6: Illustration of the thermal bubble dynamics. $\rho_{v,0}$ and $\rho_{l,0}$ are the initial vapor and liquid densities; $\rho_A$ and $\rho_B$ are the Maxwell state at the initial temperature; $\rho_{v,T}$ and $\rho_{l,T}$ are the vapor and liquid densities at time $T = 10.0$. 
Figure 7: Coalescence of two bubbles for the one-dimensional thermal Navier-Stokes-Korteweg equations: (a) density profiles and (b) temperature profiles at times $t = 0.0, 0.1, 0.5, 1.0, 2.0$ and 10.0.
Figure 8: Coalescence of two bubbles for the one-dimensional thermal Navier-Stokes-Korteweg equations: Evolution of the discrete entropy. (a) Global view; (b) Detailed view in the vicinity of $t = 2.49$. 
temperature $\theta = 0.95$, the energetically stable liquid and vapor densities are 0.487 and 0.193 respectively; the initial vapor and liquid densities are $\rho_{v,0} = 0.1$ and $\rho_{l,0} = 0.6$. Hence, the vapor phase will become denser and the liquid phase will become lighter to minimize the free energy. In the meantime, the phase transition is accompanied with latent heat release and absorption, which will change the local temperature distribution. Consequently, the shape of the free energy and the Maxwell states are changed. This coupled process will eventually reach an equilibrium state. This dynamic process is illustrated in a density-temperature phase diagram in Figure 6. In Figure 7, snapshots of the density and the temperature are depicted at times $t = 0.0, 0.1, 0.5, 1.0, 2.0$ and $10.0$. It is observed that the initial interface between the two vapor bubbles gradually vanishes, and the vapor and liquid densities are adjusted to achieve the energy-stable states. In the mean time, the temperature of this system fluctuates. The temperature first drops to about 0.876 at time $t = 1.0$, then it raises to 0.898 uniformly at time $t = 10.0$. The Maxwell states at $\theta = 0.898$ are $\rho_{v} = 0.1403$ and $\rho_{l} = 0.5546$. Figure 7 (a) shows that the density at $t = 10.0$ is very close to the Maxwell states. Since we applied periodic boundary conditions, the dissipation relation is

$$
\int_{\Omega} \frac{H(\rho_{v}^{n+1}, \theta_{v}^{n+1}) - H(\rho_{v}^{n}, \theta_{v}^{n})}{\Delta t} d\mathbf{x} \\
= - \int_{\Omega} \left( \frac{1}{\theta_{v}^{n+\frac{1}{2}}} \cdot \nabla u_{v}^{n+\frac{1}{2}} \right) \cdot \nabla \theta_{v}^{n+\frac{1}{2}} d\mathbf{x} \\
- \int_{\Omega} \frac{1}{\theta_{v}^{n+\frac{1}{2}}} \left[ \rho_{v}^{n} \right]^{4} \frac{\partial^{3} \nu_{loc}}{\partial \rho^{3}} (\rho_{v}^{n+\xi_{1}}, \theta_{v}^{n+\frac{1}{2}}) d\mathbf{x} + \int_{\Omega} \frac{1}{\theta_{v}^{n+\frac{1}{2}}} \Delta t_{n} \cdot \left[ \frac{\rho_{v}^{n}}{24} \frac{\partial^{3} H}{\partial \rho^{3}} (\rho_{v}^{n+\frac{1}{2}}, \theta_{v}^{n+\frac{1}{2}}) \right] d\mathbf{x} \\
\leq 0.
$$

The discrete mathematical entropy are plotted against time in Figure 8 (a). It can be observed that $H(\rho_{v}^{n}, \theta_{v}^{n})$ monotonically decreases with respect to time, which confirms the theoretical estimate given in Theorem 6. In Figure 8 (b), a detailed view of the discrete mathematical entropy in the vicinity of $t = 2.49$ is provided. It can be observed that the differences between the numerical solutions and the overkill solution decrease with reductions of time step sizes. To verify the time accuracy estimate, overkill solutions were first computed with $\Delta t = 1.0 \times 10^{-5}$. Then the computations were repeated with larger time steps $\Delta t = 5.0 \times 10^{-2}, 1.0 \times 10^{-2}, 5.0 \times 10^{-3}, 1.0 \times 10^{-3}$ and $5.0 \times 10^{-4}$. The errors at time $t = 1.0$ are listed in Table 2. It can be seen that the numerical solutions converge optimally in time to the overkill solutions. This again corroborates the theoretical estimates given in Theorem 7.

5 Application problems

In this section, we investigate the van der Waals fluid model by performing simulations with the numerical algorithm developed in Section 3.

Figure 9: Velocity streamlines near a single bubble at time $t = 15.0$: $\theta_{bc} = 0.85$.

5.1 Evaporation and condensation

In this example, we numerically investigate the dynamics of a single vapor bubble in the presence of temperature raise or drop on the boundary. In this study, the computational domain is restricted to a unit square $\Omega = (0,1)^2$. The center of the vapor bubble is located at the center of the domain, i.e., $C_1 = (0.5, 0.5)$; the radius of the bubble is $R_1 = 0.25$. A
hyperbolic tangent function is utilized to give the initial density profile:

\[ \rho_0(x) = 0.3545 + 0.2479 \tanh \left( \frac{d_1(x) - R_1}{2} \sqrt{\text{We}} \right), \quad (179) \]

\[ d_1(x) = |x - C_1|. \quad (180) \]

The initial velocity is set to be zero. The initial temperature is given by

\[ \theta_0(x) = 0.85, \quad \text{if } x \in \Omega, \]
\[ \theta_0(x) = \theta_{bc}, \quad \text{if } x \in \partial \Omega. \]

The boundary conditions for this problem are

\[ \nabla \rho \cdot n = 0, \quad \text{on } \partial \Omega \times (0, T), \]
\[ u = 0, \quad \text{on } \partial \Omega \times (0, T), \]
\[ \theta = \theta_{bc}, \quad \text{on } \partial \Omega \times (0, T). \]

It is known that the hyperbolic tangent function is only an approximation of the steady state solution. In the function (179), the liquid density is 0.6024 and the vapor density is 0.1066, which are very close to the Maxwell states at temperature \( \theta = 0.85 \). Hence, there will be a low-intensity velocity field generated near the interfacial region to adjust the interface profile. The phenomenon occurring near the interface is commonly referred to as the parasitic currents [?], and a snapshot of the parasitic currents at time \( t = 15.0 \) is depicted in Figure 9. If \( \theta_{bc} \neq 0.85 \), as time evolves, thermal diffusion will drive the temperature inside \( \Omega \) to \( \theta_{bc} \). This change of temperature directly leads to the change of the Maxwell states, which is observed as condensation or evaporation of the bubble. If \( \theta_{bc} > 0.85 \), the bubble will evaporate; if \( \theta_{bc} < 0.85 \), the bubble will condense.

**Ju, I do not understand this sentence. The bubble cannot evaporate because it is already vapor. Looking at Fig. 10(f) it does not look like the bubble condenses for \( \theta_{bc} < 0.85 \). This statement does not look right. Something that I think might be relevant to comment is that the lower the temperature, the stronger the separation and the larger the ratio \( \rho_l/\rho_v \).**

In Table 3, the Maxwell states at different temperatures are listed. With these values, the radius of the vapor bubble at the new stable configuration can be estimated by using the mass conservation relation. Assuming the interfacial region has measure zero, then the total mass in \( \Omega \) is

\[ 0.1066 \times 0.25^2 \pi + 0.6024 \times (1.0 - 0.25^2 \pi) = 0.6024 - 0.031 \pi. \quad (181) \]
If the Maxwell-state liquid and vapor densities at the temperature $\theta$ are denoted as $\rho^0_l$ and $\rho^0_v$. The new radius of the vapor bubble $R_{st}$ can be determined by the mass conservation relation

$$\rho^0_v \times R_{st}^2 \pi + \rho^0_l \times (1.0 - R_{st}^2 \pi) = 0.6024 - 0.031\pi,$$  \hspace{1cm} (182)

if $\rho^0_l$ and $\rho^0_v$ satisfy $\rho^0_v \leq 0.6024 - 0.031\pi \leq \rho^0_l$. If $\rho^0_l < 0.6024 - 0.031\pi$, the steady state will be a uniform liquid state with density $0.6024 - 0.031\pi$; if $0.6024 - 0.031\pi \leq \rho^0_v$, the steady state will be a uniform vapor state with density $0.6024 - 0.031\pi$. The solutions of $R_{st}$ for $\theta = 0.95, 0.90, 0.85, 0.80,$ and $0.75$ are listed in Table 3.

Table 3: The liquid and vapor densities at the Maxwell states of the van der Waals fluid model at different temperatures. The values are rounded to four decimal places. $R_{st}$ represents the steady-state vapor bubble radius with the given initial density profile (179)-(180) in the sharp interface limit. When $\theta = 0.95$, a uniform liquid state with density $\rho = 0.5050$ will form at the steady state.

In the numerical simulations, the dimensionless numbers are taken as $Re = 1.451 \times 10^3$, $We = 5.263 \times 10^5$, and $\gamma = 1.333$; the dimensionless thermal conductivity is

$$\kappa = \begin{bmatrix} 1.378 \times 10^{-3} & 0.0 \\ 0.0 & 1.378 \times 10^{-3} \end{bmatrix}.$$

The external body force $b$ and the heat source $r$ are fixed to be zero. The spatial mesh is comprised of $512^2$ quadratic NURBS elements. The simulation is integrated up to $T = 2.0 \times 10^2$ with time step size $\Delta t = 1.0 \times 10^{-3}$. In Figure 10, the density profiles at time $t = 200.0$ are depicted for $\theta_{bc} = 0.75, 0.80, 0.85, 0.90,$ and $0.95$. The solution for $\theta_{bc} = 0.95$ at $t = 200.0$ forms a uniform liquid state. From $\theta_{bc} = 0.90$ to $\theta_{bc} = 0.75$, the radius of the bubble increases with the decrease of the boundary temperature. Also, it can be observed that the interface width reduces with the decrease of the temperature, which confirms a previous estimate [?].
Figure 10: Density profiles of a single bubble under different temperature boundary conditions: (a) Initial condition, (b) $\theta_{bc} = 0.95$, (c) $\theta_{bc} = 0.90$, (d) $\theta_{bc} = 0.85$, (e) $\theta_{bc} = 0.80$, (f) $\theta_{bc} = 0.75$. 
5.2 Thermocapillary motion

Nowadays, the motion of interfaces induced by the imbalance of surface tension is generally referred to as the Marangoni effect [?]. Among the many different Marangoni effects, motion driven by the temperature gradient is of keen interest and is often specifically referred to as the thermocapillary effect. This effect is critical in understanding many complicated physical phenomena, such as boiling [?] and welding [?]. In the seminal paper [?], the authors modeled the surface tension as a function of the temperature. Under a temperature gradient, there will be an imbalance of the stress, which drives the bubble move in the negative thermal gradient direction. Under this model, the bubble velocity in the creeping flow limit was derived. Soon, this theory is coupled with the multiphase flow solvers to simulate the thermocapillary motion [?, ?]. Recently, a theoretical analysis for the thermocapillary motion was given for the van der Waals fluid [?, ?]. In those works, the interstitial working flux $\Pi$ was ignored, and hence the models they considered are totally different from the model we derived. In this section, we investigate the thermocapillary motion of a single vapor bubble in two and three-dimensions with very fine resolutions.

5.2.1 Two-dimensional thermocapillary motion

In this example, the computational domain is a two-dimensional square $\Omega = (0, 1)^2$. The boundary of $\Omega$ is partitioned into three non-overlapping subdivisions:

$$
\partial \Omega = \Gamma_v \cup \Gamma_t \cup \Gamma_b,
\Gamma_v := \partial \Omega \cap \{\{x \in \mathbb{R}^2 | x = 0\} \cup \{x \in \mathbb{R}^2 | x = 1\}\},
\Gamma_b := \partial \Omega \cap \{x \in \mathbb{R}^2 | y = 0\},
\Gamma_t := \partial \Omega \cap \{x \in \mathbb{R}^2 | y = 1\}.
$$

The initial density is given by

$$
\rho_0(x) = 0.35 + 0.25 \tanh \left( \frac{d_1(x) - 0.2}{2} \sqrt{We} \right),
$$

$$
d_1(x) = |x - C_1|,
$$

wherein the center of the static vapor bubble is $C_1 = (0.5, 0.5)$. The initial velocity is fixed to be zero and the initial temperature is

$$
\theta_0(x) = 0.85 \quad x \in \Omega \cup \Gamma_v \cup \Gamma_b,
$$
\[ \theta_0(x) = 0.87 \quad x \in \Gamma_t. \]

The boundary conditions for this problem are

\[
\begin{align*}
\nabla \rho \cdot n &= 0, & \text{on } \partial \Omega \times (0, T), \\
u &= 0, & \text{on } \partial \Omega \times (0, T), \\
\theta &= 0.85, & \text{on } \Gamma_b \times (0, T), \\
\theta &= 0.87, & \text{on } \Gamma_t \times (0, T), \\
-q \cdot n &= 0, & \text{on } \Gamma_v \times (0, T). \\
\end{align*}
\]

The dimensionless numbers and the dimensionless thermal conductivity are chosen as

\[
\begin{align*}
\text{Re} &= 1.738 \times 10^4, \\
\text{We} &= 3.277 \times 10^6, \\
\gamma &= 1.333, \\
\kappa &= \begin{bmatrix} 3.453 \times 10^{-3} & 0.0 \\ 0.0 & 3.453 \times 10^{-3} \end{bmatrix}. \\
\end{align*}
\]

Figure 11: Thermocapillary motion of a single bubble in a two-dimensional square: Initial conditions for density (a) and temperature (b).

The spatial discretization is comprised of 1024\(^2\) quadratic NURBS functions. The time integration is performed with a fixed step size \( \Delta t = 5.0 \times 10^{-4} \) up to the final time \( T = 500.0 \). In Figure 11, the initial density and temperature profiles are illustrated. In Figures 12-13, the density, temperature, and velocity fields are depicted at various time steps. It is noted
Figure 12: Thermocapillary motion of a single bubble in a two-dimensional square: Solutions at $t = 5.0 \times 10$ (left column) and $t = 2.0 \times 10^2$ (right column). The first row depicts the density profiles; the second row depicts the temperature profiles; the third row visualizes the velocity streamlines.
Figure 13: Thermocapillary motion of a single bubble in a two-dimensional square: Solutions at $t = 3.0 \times 10^2$ (left column) and $t = 5.0 \times 10^2$ (right column). The first row depicts the density profiles; the second row depicts the temperature profiles; the third row visualizes the velocity streamlines.
that there is a velocity field generated immediately after the simulation starts. The velocity drives the vapor bubble migrate toward the negative thermal gradient direction. Eventually, the vapor bubble attaches the heated wall boundary and forms a hemispheric shape, as is shown in Figure 13 (b). It can be observed that, in the liquid phase, there is a temperature gradient generated between the heated top boundary and the cooled bottom boundary. Inside the vapor bubble, the temperature distribution remains homogeneous throughout the whole process. The homogeneous temperature inside the vapor bubble was analyzed in [?] and was attributed to the latent heat diffusion.

5.2.2 Three-dimensional thermocapillary motion

As a second example, a three-dimensional numerical simulation is performed. The computation domain is restricted to be $\Omega = (0, 0.5) \times (0, 0.5) \times (0, 1)$. The boundary of $\Omega$ is partitioned into three non-overlapping subdivisions:

$$\partial \Omega = \Gamma_t \cup \Gamma_b \cup \Gamma_v,$$

$$\Gamma_b := \partial \Omega \cap \{x \in \mathbb{R}^2 | z = 0\},$$

$$\Gamma_t := \partial \Omega \cap \{x \in \mathbb{R}^2 | z = 1\},$$

$$\Gamma_v := \partial \Omega \cap \left\{ \{x \in \mathbb{R}^2 | x = 0\} \cup \{x \in \mathbb{R}^2 | x = 0.5\} \cup \{x \in \mathbb{R}^2 | y = 0\} \cup \{x \in \mathbb{R}^2 | y = 0.5\} \right\}.$$

The center of the vapor bubble is initially located at $C_1 = (0.25, 0.25, 0.3)$, and the bubble radius is 0.2. The initial density and velocity are

$$\rho_0(x) = 0.35 + 0.25 \tanh \left( \frac{d_1(x) - 0.2}{2 \sqrt{We}} \right),$$

$$d_1(x) = |x - C_1|,$$

$$u_0(x) = 0.$$

The initial temperature is

$$\theta_0(x) = 0.85, \quad x \in \Omega \cup \Gamma_v \cup \Gamma_b,$$

$$\theta_0(x) = 0.87, \quad x \in \Gamma_t.$$
The boundary conditions for this problem are

\[ \nabla \rho \cdot n = 0, \quad \text{on } \partial \Omega \times (0, T), \]
\[ \mathbf{u} = 0, \quad \text{on } \partial \Omega \times (0, T), \]
\[ \theta = 0.85, \quad \text{on } \Gamma_b \times (0, T), \]
\[ \theta = 0.87, \quad \text{on } \Gamma_t \times (0, T), \]
\[ -\mathbf{q} \cdot n = 0, \quad \text{on } \Gamma_v \times (0, T). \]

The dimensionless numbers and the dimensionless thermal conductivity are taken as

\[ \text{Re} = 3.570 \times 10^3, \]
\[ \text{We} = 1.383 \times 10^5, \]
\[ \gamma = 1.333, \]
\[ \kappa = \begin{bmatrix} 1.681 \times 10^{-2} & 0.0 & 0.0 \\ 0.0 & 1.681 \times 10^{-2} & 0.0 \\ 0.0 & 0.0 & 1.681 \times 10^{-2} \end{bmatrix}. \]

The spatial mesh for this problem is comprised of \(128 \times 128 \times 256\) quadratic NURBS elements. The time integration is performed up to the final time \(T = 200\) with a fixed time step size of \(\Delta t = 1.0 \times 10^{-3}\). Figures 14-16 present snapshots of density isosurfaces, velocity streamlines, and temperature contours at various slices. As soon as the simulation starts, there is a temperature gradient generated in the liquid phase; the temperature field inside the vapor bubble remains nearly homogeneous. Similarly to the two-dimensional counterpart, there is a velocity field generated instantaneously after the top boundary is heated. The initial static vapor bubble is then driven by the velocity toward the heated boundary. At about \(t = 160\), the vapor bubble touches the top heated boundary. At \(t = 200\), a vapor layer is formed, which separates the heated wall boundary from the bulk liquid phase. The velocity magnitude at \(t = 200\) is uniformly small. The solutions shown in Figure 16 (c) and (d) can be regarded to be very close to the steady state solutions.

### 5.3 Boiling

Boiling is a thermally induced phase transition process in which new liquid-vapor interfaces are generated in a bulk liquid region [?, ?]. The new interfaces may form from discrete cavities on heated surfaces, which is called nucleate boiling, or from a stable superheated vapor layer, which is referred to as film boiling. Nucleate boiling is characterized by isolated
Figure 14: Three-dimensional thermocapillary motion of a single bubble: (a) density isosurface at $t = 0.0$, (b) temperature on various slices at $t = 0.0$, (c) density isosurface and streamlines at $t = 40.0$, (b) temperature on various slices at $t = 40.0$. 
Figure 15: Three-dimensional thermocapillary motion of a single bubble: (a) density isosurface and streamlines at $t = 80.0$, (b) temperature on various slices at $t = 80.0$, (c) density isosurface and streamlines at $t = 120.0$, (d) temperature on various slices at $t = 120.0$. 
Figure 16: Three-dimensional thermocapillary motion of a single bubble: (a) density isosurface and streamlines at $t = 160.0$, (b) temperature on various slices at $t = 160.0$, (c) density and streamlines isosurface at $t = 200.0$, (b) temperature on various slices at $t = 200.0$. 
bubble generation and is the most efficient mode in heat transfer. If the surface temperature increases, bubbles on the surface tend to move horizontally and merge together to form a vapor layer. Beyond a certain critical surface temperature, a stable vapor film may eventually form between the heated solid surface and the bulk liquid phase, and vapor bubbles detach from the layer periodically. Film boiling is quite dangerous and should be avoided in most industry facilities because of the heat accumulated in the vapor film. Boiling has been extensively employed in energy conversion facilities, such as power generators, cooling systems for electronic devices, and petroleum refineries. Despite its importance in industry, the fundamental mechanism of boiling is still not well understood, as was admitted by physicists \[?\, ?\] and engineers \[?, ?\]. To date, knowledge about boiling is mainly obtained by correlating experimental data to empirical formulas. In view of its disparity of spatiotemporal scales and elusive nature of many subprocesses, a predictive model for boiling is highly important for engineering designs.

There have been a few but growing numerical studies of boiling in the past years. Film boiling is regarded as most amenable to modeling, since its governing mechanism is principally the Rayleigh-Taylor instability. A multiphase solver that can simulate the Rayleigh-Taylor instability should be capable of simulating film boiling. Existing numerical simulations have been carried out by the level set method \[?\], the front tracking method \[?\], and the volume-of-fluid method \[?\]. In those numerical studies, the simulations all started with a preexisting perturbed flat interface as the initial condition. In other words, none of those methods captured the film generation process. On the other side, very few simulations of nucleate boiling have been performed. The reason is that more physical mechanisms are involved in this phenomenon. A credible nucleate boiling solver is expected to be capable of describing the creation of new interfaces near the nucleation sites, handling the Rayleigh-Taylor instability and the Rayleigh-Bénard instability, and tracking the moving interfaces of bubbles and free surfaces. In \[?\], the authors have studied the nucleate boiling by specifically designing a model for the region near the nucleate cavities. This approach destroys the conservation structure and relies on empirical data, including the bubble release rate, the nucleation site density, etc. In this work, we simulate boiling flows in two and three dimensions, using the Navier-Stokes-Korteweg equations. To obtain successful boiling simulations, there are several additional modeling considerations. First, the transport parameters are chosen to be density dependent in order to differentiate the properties of the liquid and vapor phases. Specifically, the dimensionless viscosity \(\tilde{\mu}\) and the thermal conductivity \(\kappa\) are larger in the liquid region than those in the vapor region. In our simulations, these two parameters are
taken as

\[ \bar{\mu} = C_{\mu}^\text{boil} \rho, \]
\[ \kappa = C_{\kappa}^\text{boil} \rho I, \]

with \( C_{\mu}^\text{boil} \) and \( C_{\kappa}^\text{boil} \) being constants independent of \( \rho \). Second, the gravity effect should be taken into account to generate the buoyant effect. The dimensionless body force \( b \) is chosen as

\[ b = (0; 0; -0.025)^T, \]

for the three-dimensional case and

\[ b = (0; -0.025)^T, \]

for the two-dimensional case. Third, the boundary conditions are designed as follows. The ninety-degree contact angle boundary condition is used for the density variable and the slip boundary condition is applied to the velocity field. To specify the boundary condition for the temperature, the boundary \( \partial \Omega \) is divided into three non-overlapping parts:

\[ \partial \Omega = \Gamma_t \cup \Gamma_b \cup \Gamma_v, \]
\[ \Gamma_t = \{ x \in \partial \Omega | n(x) \cdot b < 0 \}, \]
\[ \Gamma_b = \{ x \in \partial \Omega | n(x) \cdot b > 0 \}, \]
\[ \Gamma_v = \{ x \in \partial \Omega | n(x) \cdot b = 0 \}. \]

With the above partition, the boundary condition for \( \theta \) is

\[ \theta = \theta_h, \quad \text{on } \Gamma_b \times (0, T), \]
\[ \theta = \theta_c, \quad \text{on } \Gamma_t \times (0, T), \]
\[ -q \cdot n = 0, \quad \text{on } \Gamma_v \times (0, T). \]

In the numerical calculations, the Dirichlet boundary conditions for \( \theta \) on \( \Gamma_b \) and \( \Gamma_t \) should be transformed to the Dirichlet boundary conditions for the entropy variable \( Y_5 \) as

\[ Y_5 = Y_{5,h} = -\frac{1}{\theta_h}, \quad \text{on } \Gamma_b \times (0, T), \]
\[ Y_5 = Y_{5,c} = -\frac{1}{\theta_c}, \quad \text{on } \Gamma_t \times (0, T). \]
Throughout, the Dirichlet data are chosen as $\theta_h = 0.950$ and $\theta_c = 0.775$. In real situations, the temperature on the solid surface cannot be evenly distributed due to surface unevenness. This effect is modeled by adding perturbations to the Dirichlet data:

$$Y_{5,h} = -\frac{1}{0.950} + \delta Y_{5,h}(x),$$
$$Y_{5,c} = -\frac{1}{0.775} + \delta Y_{5,c}(x),$$

wherein $\delta Y_{5,h}(x)$ and $\delta Y_{5,c}(x)$ are scalar perturbation functions that mimic the uneven temperature distribution on the solid surface. As for the initial conditions, the initial density and temperature are given by hyperbolic tangent functions; the initial velocity is zero. The detailed formulations of the initial conditions are given in the subsequent subsections. These conditions represent a static free surface, with liquid in the bottom region and vapor in the top region. It is worth emphasizing that the initial liquid and vapor densities are uniform with no perturbations. In contrast to existing boiling models, there is no artificial manipulation used to serve as boiling onset in this model. The following results will show that the vapor bubble or the vapor film may form automatically without preexisting nuclei simply due to local temperature variations. Another appealing property of this model is that nucleate boiling and film boiling can be simulated within a unified framework by tuning dimensionless parameters. These features should be credited to the thermodynamically consistent nature of the model and the algorithm. It is expected that this new methodology may lead to a predictive tool for the boiling phenomenon.

The rest of this section is organized as follows. In Section 5.3.1, we perform a mesh sensitivity test. In Sections 5.3.2 and 5.3.3, two-dimensional nucleate boiling and two-dimensional film boiling are numerically studied. Following that, a three-dimensional boiling simulation is investigated in Section 5.3.4.

### 5.3.1 Two-dimensional mesh sensitivity test

Before we start simulating practical examples, a mesh sensitivity test is performed to examine the mesh independence of the solution. The simulation domain is $\Omega = (0, 1) \times (0, 0.5)$. The material parameters are chosen as

$$\text{We} = 2.103 \times 10^6,$$
$$\gamma = 1.333,$$
$$C_{\mu}^{\text{boil}} = 2.298 \times 10^{-4},$$
$$C_{\kappa}^{\text{boil}} = 3.448 \times 10^{-5}.$$
The initial conditions for this problem are

\[ \rho_0(x) = 0.3660 - 0.2971 \tanh \left( \frac{x_2 - 0.35}{2} \sqrt{We} \right), \]

\[ u_0(x) = 0, \]

\[ \theta_0(x) = 0.775. \]

The perturbation for the temperature on the boundary \( \delta_{Y_{5,h}}(x) \) and \( \delta_{Y_{5,c}}(x) \) are

\[ \delta_{Y_{5,h}}(x) = 5.0 \times 10^{-2} \sin(10\pi x), \]

\[ \delta_{Y_{5,c}}(x) = 5.0 \times 10^{-3} \sin(10\pi x). \]

The problem is integrated up to \( T = 35.0 \) with time step size \( \Delta t = 1.0 \times 10^{-4} \). We use four different spatial meshes: \( 800 \times 400 \) quadratic NURBS elements, \( 1024 \times 512 \) quadratic NURBS elements, \( 2048 \times 1024 \) quadratic NURBS elements, and \( 4096 \times 2048 \) quadratic NURBS elements. The density profiles at \( t = 35 \) are depicted in Figure 17. As can be seen, the density profiles are similar for all four meshes. In the coarsest mesh, the shape of the second bubble attached to the bottom (from left to right) is significantly different from those in the...
finer meshes. The solutions shown in Figure 17 (c) and (d) are indistinguishable. Therefore, in the following two-dimensional calculations, we use $2048 \times 1024$ quadratic NURBS elements to save computation time without losing accuracy.

5.3.2 Two-dimensional nucleate boiling

Figure 18: Initial conditions of the two-dimensional boiling simulation: (a) density, (b) temperature.

In this example, we simulate boiling flows in a two-dimensional rectangular domain $\Omega = (0, 1) \times (0, 0.5)$. The material parameters are chosen as

\[
\begin{align*}
    \text{We} &= 8.401 \times 10^6, \\
    \gamma &= 1.333, \\
    C_{\mu}^{\text{boil}} &= 1.150 \times 10^{-4}, \\
    C_{\kappa}^{\text{boil}} &= 1.725 \times 10^{-5}.
\end{align*}
\]
Figure 19: Solutions of the two-dimensional nucleate boiling simulation at \( t = 1.25 \): (a) density, (b) temperature, (c) velocity streamlines.
Figure 20: Solutions of the two-dimensional nucleate boiling simulation at $t = 18.75$: (a) density, (b) temperature, (c) velocity streamlines.
Figure 21: Solutions of the two-dimensional nucleate boiling simulation at $t = 31.25$: (a) density, (b) temperature, (c) velocity streamlines.
Figure 22: Solutions of the two-dimensional nucleate boiling simulation at $t = 62.5$: (a) density, (b) temperature, (c) velocity streamlines.
Figure 23: Solutions of the two-dimensional nucleate boiling simulation at $t = 100.0$: (a) density, (b) temperature, (c) velocity streamlines.
The initial conditions for this problem are

\[ \rho_0(x) = 0.3660 - 0.2971 \tanh \left( \frac{x_2 - 0.35}{2} \sqrt{\text{We}} \right), \quad \tag{183} \]
\[ u_0(x) = 0, \quad \tag{184} \]
\[ \theta_0(x) = 0.775. \quad \tag{185} \]

In Figure 18, the initial conditions for density and temperature have been illustrated. The perturbation for the temperature on the boundary \( \delta Y_{5,h}(x) \) and \( \delta Y_{5,c}(x) \) are uniform random distributions and satisfy

\[ \delta Y_{5,h}(x) \in [-5.0 \times 10^{-2}, 5.0 \times 10^{-2}], \]
\[ \delta Y_{5,c}(x) \in [-5.0 \times 10^{-3}, 5.0 \times 10^{-3}]. \]

The spatial mesh consists of 2048 \( \times \) 1024 quadratic NURBS elements. The problem is integrated up to the final time \( T = 1.0 \times 10^2 \) with time step fixed as \( \Delta t = 5.0 \times 10^{-4} \).

In Figures 19-23, snapshots of the density, temperature, and velocity streamlines are depicted. In Figure 19, it can be observed that tiny vapor bubbles are generated at discrete sites of the heated wall surface during the initial times. These small bubbles grow in size, and some bubbles merge together to form larger bubbles, as is shown in Figure 20. The increase of bubble size leads to the growth of the buoyant effect. Beyond a certain critical point, the bubbles get detached from the bottom boundary and rise upward. At about \( t = 18.75 \), the first three bubbles get detached from the bottom. More bubbles are generated on the bottom surface in the mean time. Figures 21 and 22 show the moments when two bubbles are about to reach the free surface. Interestingly, from Figures 22 and 23, small droplets can be observed as a result of the breakage of the liquid film when the vapor bubbles reach the free surface. There are totally 30 bubbles formed in the time interval of \( 0 < t < 100 \).

5.3.3 Two-dimensional film boiling

In the third example, the same two-dimensional problem considered in the preceding section is simulated again with a different parameter \( C_{\mu_{\text{boil}}} \). Here, the parameter \( C_{\mu_{\text{boil}}} \) is chosen to be \( 4.600 \times 10^{-4} \), which is four times larger than that of the previous example. Since the fluid motion in this example is slower, the simulation is integrated in time up to \( T = 5.0 \times 10^2 \). All the other conditions are identical to those of the previous case. In Figures 24-28, snapshots of the density, temperature, and velocity streamlines at different time steps are presented. Once the simulation starts, a thin vapor film is gradually generated at the bottom during the
Figure 24: Solutions of the two-dimensional film boiling simulation at $t = 100.0$: (a) density, (b) temperature, (c) velocity streamlines.
Figure 25: Solutions of the two-dimensional film boiling simulation at $t = 175.0$: (a) density, (b) temperature, (c) velocity streamlines.
Figure 26: Solutions of the two-dimensional film boiling simulation at $t = 200.0$: (a) density, (b) temperature, (c) velocity streamlines.
Figure 27: Solutions of the two-dimensional film boiling simulation at $t = 225.0$: (a) density, (b) temperature, (c) velocity streamlines.
Figure 28: Solutions of the two-dimensional film boiling simulation at $t = 500.0$: (a) density, (b) temperature, (c) velocity streamlines.
early stage of the simulation (see Figure 24). As time evolves, the interface becomes unstable and there are three mushroom-shaped vapor bubbles formed, as are shown in Figures 25 and 26. From $t = 200.0$ to $t = 225.0$, the first two vapor bubbles pinch off from the vapor film and rise upward in ellipsoidal shapes. As the bubbles get released from the vapor film, two stems are left on the vapor film, which serve as onsets of new bubbles. This process repeats itself periodically. Till the final time $t = 500.0$, there are totally seven bubbles detached from the vapor film. The average bubble release rate for this film boiling problem is much less than that of the nucleate boiling counterpart.

5.3.4 Three-dimensional boiling

As the last example, we simulate the Navier-Stokes-Korteweg equations in a three-dimensional domain $\Omega = (0, 1) \times (0, 0.5) \times (0, 0.25)$. The material properties are chosen as

\[
\begin{align*}
  \text{We} & = 6.533 \times 10^5, \\
  \gamma & = 1.333, \\
  C^\text{boil}_\mu & = 1.289 \times 10^{-4}, \\
  C^\text{boil}_\kappa & = 7.732 \times 10^{-5}.
\end{align*}
\]

The initial conditions for this three-dimensional problem are similar to those of the two-dimensional problem, except the free surface is defined by $x_3 = 0.15$:

\[
\begin{align*}
  \rho_0(\mathbf{x}) & = 0.33565 - 0.26675 \tanh \left( \frac{x_3 - 0.15}{2} \sqrt{\text{We}} \right), \\
  \mathbf{u}_0(\mathbf{x}) & = 0, \\
  Y_{5,0}(\mathbf{x}) & = -1.2334 - 0.0569 \tanh \left( \frac{x_3 - 0.15}{2} \sqrt{\text{We}} \right).
\end{align*}
\]

The perturbation for the temperature on the boundary $\delta Y_{5,h}(\mathbf{x})$ and $\delta Y_{5,c}(\mathbf{x})$ are uniform random distributions and satisfy

\[
\begin{align*}
  \delta Y_{5,h}(\mathbf{x}) & \in [-5.0 \times 10^{-2}, 5.0 \times 10^{-2}], \\
  \delta Y_{5,c}(\mathbf{x}) & \in [-5.0 \times 10^{-3}, 5.0 \times 10^{-3}].
\end{align*}
\]

The spatial mesh consists of $600 \times 300 \times 150$ quadratic NURBS elements. The problem is integrated in time up to $T = 20.0$ with a fixed time step size $\Delta t = 2.0 \times 10^{-3}$.

Remark 16. The initial condition for $Y_5$ is in fact a hyperbolic tangent interpolation of
\[ \theta = 0.85 \text{ for } x_2 < 0.15 \text{ and } \theta = 0.775 \text{ for } x_2 > 0.15. \]

Figure 29: Initial conditions of the three-dimensional boiling: (a) density isosurfaces, (b) temperature isosurfaces.

In Figures 29-34, snapshots of density isosurfaces, velocity streamlines, and temperature isosurfaces are presented at times \( t = 0.0, 0.6, 5.0, 11.0, 14.0 \) and 20.0. At the initial stage, there is an unstable vapor film formed over the heated wall surface (see Figure 30). This film soon separates into isolated vapor bubbles located at random sites on the bottom
Figure 30: Solutions of the three-dimensional boiling at time $t = 0.6$: (a) density isosurfaces and velocity streamlines, (b) temperature isosurfaces.
Figure 31: Solutions of the three-dimensional boiling at time $t = 5.0$: (a) density isosurfaces and velocity streamlines, (b) temperature isosurfaces.
Figure 32: Solutions of the three-dimensional boiling at time $t = 11.0$: (a) density isosurfaces and velocity streamlines, (b) temperature isosurfaces.
Figure 33: Solutions of the three-dimensional boiling at time $t = 14.0$: (a) density isosurfaces and velocity streamlines, (b) temperature isosurfaces.
Figure 34: Solutions of the three-dimensional boiling at time $t = 20.0$: (a) density isosurfaces and velocity streamlines, (b) temperature isosurfaces.
surface (see Figures 31 and 32). With the growth of the bubbles, the thermal energy is conducted through the vapor region. Since the simulation domain is very shallow in the vertical direction, these bubbles reach the free surface before they get fully detached from the bottom. When these high-temperature vapor bubbles reach the cooled top surface, they condense into liquid droplets instantaneously (see Figure 33). At $t = 20.0$, a second round of vapor bubbles is clearly generated on the bottom and the liquid droplets on the top surface get merged together. There is a complex Rayleigh-Bénard mixing structure for the temperature field, as is shown in Figure 34.

6 Conclusions and future work

In this work, we presented a comprehensive suite of theoretical and numerical methodology for the study of liquid-vapor two-phase flows. The contributions are elaborated as follows.

A continuum mechanic modeling framework for multiphase flows has been constructed. In its derivation, the microforce theory \cite{[1]} is adopted with the objective of accommodating non-local effects. This modeling framework enjoys several appealing properties. First, all constitutive relations are represented in terms of a thermodynamically potential. Therefore, the modeling work is reduced to the design of a proper form of the thermodynamic potential. Second, the framework intrinsically satisfies the second law of thermodynamics. Third, in this framework, some previously mysterious modeling terms find rational mechanics explanations as a result of the Coleman-Noll procedure. For example, the “interstitial working flux” \cite{2} is the power expenditure of the microstress. Within this framework, the Navier-Stokes-Korteweg equations and the compressible Navier-Stokes equations are recovered by proper choices of the Helmholtz free energy functional.

A thermodynamically consistent numerical scheme for the Navier-Stokes-Korteweg equations is constructed in this work. For the van der Waals fluid model, the definition of the entropy variables is generalized to the functional setting to overcome the difficulty induced by the non-convexity of the entropy function. Interestingly, the functional entropy variables for the van der Waals fluid are formally identical to those of the perfect gas model. The difference is that the entropy variables are not merely algebraic change-of-variables, but rather they are mappings from the conservation variables to their dual spaces. An alternative statement of the strong problem is devised such that the entropy variables are weakly enforced in the test function spaces. In doing so, the weak problem is guaranteed to be entropy dissipative, as is shown in Theorem 4. In addition to the spatial discretization, new time integration schemes are developed based on a family of new quadrature rules \cite{3}. In contrast to the traditional temporal schemes \cite{4}, the new time integration schemes do not
require the convexity property of the entropy function. Essentially, the new schemes can be viewed as a second-order perturbation to the mid-point rule. The second-order perturbation guarantees that the temporal approximation is provably entropy dissipative. The theoretical estimates have been numerically verified by comparing solutions with manufactured solutions and overkill solutions.

The new model and the new algorithm have been applied to investigate a variety of application problems, including evaporation, condensation, thermocapillarity, and boiling flows. In particular, the advantage of the diffuse-interface method is demonstrated by the two and three-dimensional boiling simulations. Our approach enjoys several desirable properties. First, the dependency on empirical knowledge and assumptions are significantly reduced. In contrast, existing boiling models rely heavily on the empirical data and sometimes introduce artificial modeling terms. Second, our approach provides a unified modeling framework for both nucleate boiling and film boiling. It is optimistic that our methodology may provide a predictive tool for a wide spectrum of the boiling phenomenon.

Based on our current work, there are several promising research directions for future work. The Navier-Stokes-Korteweg equations are believed to be applicable to simulating cavitating flows, which is the liquid-vapor phase transition induced by pressure variations. A potential challenge for this simulation is a proper design of the open boundary conditions. The van der Waals model can be further improved to give more accurate material descriptions. Recently, new models have been introduced [?], and we anticipate that applying these new equation-of-state may lead to better results in comparison with the van der Waals model. On the computation side, the anisotropic structure of the solutions makes the adaptive isogeometric analysis techniques [?, ?] highly desirable.
