## 6.1 POLYNOMIAL ARITHMETIC

- **Why study polynomial arithmetic?**

**For the very simple reason that we can represent a bit pattern by a polynomial in, say, the variable  $x$ . Each power of  $x$  in the polynomial can stand for a bit position in a bit pattern.**

For example, we can represent the bit pattern 111 by the polynomial  $x^2 + x + 1$ . On the other hand, the bit pattern 101 would be represented by the polynomial  $x^2 + 1$  and the pattern 011 by the polynomial  $x + 1$ . Since all the bits in 111 are set, we have all powers of  $x$  up to 2 in the corresponding polynomial. On the other hand, in the bit pattern 101, the second bit is not set, so the coefficient of  $x$  in the polynomial is zero, which results in the polynomial  $x^2 + 1$ . Finally, in the bit pattern 011, since only the two least significant bits are set, the polynomial becomes  $x + 1$ .

**As you will see in this lecture, this ploy of representing a bit pattern with a polynomial will allow us to create a finite field with bit patterns.**

- In general, a polynomial is an expression of the form

$$a_n x^n + a_{n-1} x^{n-1} + \dots + a_1 x + a_0$$

for some non-negative integer  $n$  and where the **coefficients**  $a_0, a_1, \dots, a_n$  are drawn from some designated set  $S$ .  $S$  is called the **coefficient set**.

- When  $a_n \neq 0$ , we have a polynomial of degree  $n$ .
- A **zeroth-degree** polynomial is called a **constant polynomial**.
- **Polynomial arithmetic** deals with the addition, subtraction, multiplication, and division of polynomials.
- Note that we have **no interest in evaluating the value of a polynomial** for any value of the variable  $x$ .

## 6.2 ARITHMETIC OPERATIONS ON POLYNOMIALS

- We can add two polynomials:

$$\begin{aligned}f(x) &= a_2x^2 + a_1x + a_0 \\g(x) &= b_1x + b_0 \\f(x) + g(x) &= a_2x^2 + (a_1 + b_1)x + (a_0 + b_0)\end{aligned}$$

- We can subtract two polynomials:

$$\begin{aligned}f(x) &= a_2x^2 + a_1x + a_0 \\g(x) &= b_3x^3 + b_0 \\f(x) - g(x) &= -b_3x^3 + a_2x^2 + a_1x + (a_0 - b_0)\end{aligned}$$

- We can multiply two polynomials:

$$\begin{aligned}f(x) &= a_2x^2 + a_1x + a_0 \\g(x) &= b_1x + b_0 \\f(x) \times g(x) &= a_2b_1x^3 + (a_2b_0 + a_1b_1)x^2 + (a_1b_0 + a_0b_1)x + a_0b_0\end{aligned}$$

- We can divide two polynomials (result obtained by long division):

$$\begin{aligned} f(x) &= a_2x^2 + a_1x + a_0 \\ g(x) &= b_1x + b_0 \\ f(x) / g(x) &= ? \end{aligned}$$

[Back to TOC](#)

## 6.3 DIVIDING ONE POLYNOMIAL BY ANOTHER USING LONG DIVISION

- Let's say we want to divide the polynomial  $8x^2 + 3x + 2$  by the polynomial  $2x + 1$ :
- In this example, our **dividend** is  $8x^2 + 3x + 2$  and the **divisor** is  $2x + 1$ . We now need to find the **quotient**.
- Long division for polynomials consists of the following steps:
  - Arrange both the dividend and the divisor in the descending powers of the variable.
  - Divide the first term of the dividend by the first term of the divisor and write the result as the first term of the quotient. In our example, the first term of the dividend is  $8x^2$  and the first term of the divisor is  $2x$ . So the first term of the quotient is  $4x$ .
  - Multiply the divisor with the quotient term just obtained and arrange the result under the dividend so that the same powers of  $x$  match up. Subtract the expression just laid out from the dividend. In our example,  $4x$  times  $2x + 1$  is

$8x^2 + 4x$ . Subtracting this from the dividend yields  $-x + 2$ .

– Consider the result of the above subtraction as the new dividend and go back to the first step. (The new dividend in our case is  $-x + 2$ ).

- In our example, dividing  $8x^2 + 3x + 2$  by  $2x + 1$  yields a **quotient** of  $4x - 0.5$  and a **remainder** of 2.5.
- Therefore, we can write

$$\frac{8x^2 + 3x + 2}{2x + 1} = 4x - 0.5 + \frac{2.5}{2x + 1}$$

Back to TOC

## 6.4 ARITHMETIC OPERATIONS ON POLYNOMIALS WHOSE COEFFICIENTS BELONG TO A FINITE FIELD

- Let's consider the set of all polynomials whose coefficients belong to the finite field  $Z_7$  (which is the same as  $GF(7)$ ). (See Section 5.5 of Lecture 5 for the  $GF(p)$  notation.) Recall from the previous lecture that the Additive Inverses (**AI**) and the Multiplicative Inverses (**MI**) in this set can be displayed as:

$Z_7$ :	0	1	2	3	4	5	6
AI:	0	6	5	4	3	2	1
MI:	–	1	4	5	2	3	6

- Here is an example of **adding** two such polynomials:

$$\begin{aligned}
 f(x) &= 5x^2 + 4x + 6 \\
 g(x) &= 2x + 1 \\
 f(x) + g(x) &= 5x^2 + 6x
 \end{aligned}$$

- Here is an example of **subtracting** two such polynomials:

$$\begin{aligned} f(x) &= 5x^2 + 4x + 6 \\ g(x) &= 2x + 1 \\ f(x) - g(x) &= 5x^2 + 2x + 5 \end{aligned}$$

since the additive inverse of 2 in  $Z_7$  is 5 and that of 1 is 6. So  $4x - 2x$  is the same as  $4x + 5x$  and  $6 - 1$  is the same as  $6 + 6$ , with both additions modulo 7.

- Here is an example of **multiplying** two such polynomials:

$$\begin{aligned} f(x) &= 5x^2 + 4x + 6 \\ g(x) &= 2x + 1 \\ f(x) \times g(x) &= 3x^3 + 6x^2 + 2x + 6 \end{aligned}$$

- Here is an example of **dividing** two such polynomials:

$$\begin{aligned} f(x) &= 5x^2 + 4x + 6 \\ g(x) &= 2x + 1 \\ f(x) / g(x) &= 6x + 6 \end{aligned}$$

You can establish the last result trivially by multiplying the divisor  $2x + 1$  with the quotient  $6x + 6$ , while making sure that you multiply the coefficients in  $Z_7$ . You will see that this

product equals the dividend  $5x^2 + 4x + 6$ . As to how you can get the result through actual division is shown in the next section.

## 6.5 DIVIDING POLYNOMIALS DEFINED OVER A FINITE FIELD

- First note that we say that a polynomial is **defined over a field** if all its coefficients are drawn from the field. It is also common to use the phrase **polynomial over a field** to convey the same meaning.
- Dividing polynomials defined over a finite field is a little bit more frustrating than performing other arithmetic operations on such polynomials. Now your mental gymnastics must include both additive inverses and multiplicative inverses.
- Consider again the polynomials defined over  $GF(7)$ .
- Let's say we want to divide  $5x^2 + 4x + 6$  by  $2x + 1$ .
- In a long division, we must start by dividing  $5x^2$  by  $2x$ . This requires that we divide 5 by 2 in  $GF(7)$ . Dividing 5 by 2 is the same as multiplying 5 by the multiplicative inverse of 2. Multiplicative inverse of 2 is 4 since  $2 \times 4 \pmod{7}$  is 1. So we have

$$\frac{5}{2} = 5 \times 2^{-1} = 5 \times 4 = 20 \pmod{7} = 6$$

Therefore, the first term of the quotient is  $6x$ . Since the product of  $6x$  and  $2x + 1$  is  $5x^2 + 6x$ , we need to subtract  $5x^2 + 6x$  from the dividend  $5x^2 + 4x + 6$ . The result is  $(4 - 6)x + 6$ , which (since the additive inverse of 6 is 1) is the same as  $(4 + 1)x + 6$ , and that is the same as  $5x + 6$ .

- Our new dividend for the next round of long division is therefore  $5x + 6$ . To find the next quotient term, we need to divide  $5x$  by the first term of the divisor, that is by  $2x$ . Reasoning as before, we see that the next quotient term is again 6.
- The final result is that when the coefficients are drawn from the set  $GF(7)$ ,  $5x^2 + 4x + 6$  divided by  $2x + 1$  yields a quotient of  $6x + 6$  and the remainder is zero.
- So we can say that as a polynomial defined over the field  $GF(7)$ ,  $5x^2 + 4x + 6$  is a product of two factors,  $2x + 1$  and  $6x + 6$ . We can therefore write

$$5x^2 + 4x + 6 = (2x + 1) \times (6x + 6)$$

Back to TOC

## 6.6 LET'S NOW CONSIDER POLYNOMIALS DEFINED OVER $GF(2)$

- Recall from Section 5.5 of Lecture 5 that the notation  $GF(2)$  means the same thing as  $Z_2$ . We are obviously talking about arithmetic modulo 2.
- **First of all,  $GF(2)$  is a sweet little finite field.** Recall that the number 2 is the **first** prime. [For a number to be prime, it must have exactly two **distinct** divisors, 1 and itself.]
- $GF(2)$  consists of the set  $\{0, 1\}$ . The two elements of this set obey the following addition and multiplication rules:

$$\begin{array}{l} 0 + 0 = 0 \\ 0 + 1 = 1 \\ 1 + 0 = 1 \\ 1 + 1 = 0 \end{array}$$

$$\begin{array}{l} 0 \times 0 = 0 \\ 0 \times 1 = 0 \\ 1 \times 0 = 0 \\ 1 \times 1 = 1 \end{array}$$

$$\begin{array}{l} 0 - 0 = 0 \\ 1 - 0 = 1 \\ 0 - 1 = 0 + 1 = 1 \\ 1 - 1 = 1 + 1 = 0 \end{array}$$

- So the addition over  $GF(2)$  is equivalent to the logical XOR

operation, and multiplication to the logical AND operation.

- Examples of polynomials defined over  $GF(2)$ :

$$x^3 + x^2 - 1$$

$$-x^5 + x^4 - x^2 + 1$$

$$x + 1$$

[Back to TOC](#)

## 6.7 ARITHMETIC OPERATIONS ON POLYNOMIALS OVER $GF(2)$

- Here is an example of adding two such polynomials:

$$\begin{aligned}f(x) &= x^2 + x + 1 \\g(x) &= x + 1 \\f(x) + g(x) &= x^2\end{aligned}$$

- Here is an example of subtracting two such polynomials:

$$\begin{aligned}f(x) &= x^2 + x + 1 \\g(x) &= x + 1 \\f(x) - g(x) &= x^2\end{aligned}$$

- Here is an example of multiplying two such polynomials:

$$\begin{aligned}f(x) &= x^2 + x + 1 \\g(x) &= x + 1 \\f(x) \times g(x) &= x^3 + 1\end{aligned}$$

- Here is an example of dividing two such polynomials:

$$\begin{aligned}f(x) &= x^2 + x + 1 \\g(x) &= x + 1 \\f(x) / g(x) &= x + \frac{1}{x + 1}\end{aligned}$$

If you multiply the divisor  $x + 1$  with the quotient  $x$ , you get  $x^2 + x$  that when added to the remainder 1 gives us back the dividend  $x^2 + x + 1$ .

[Back to TOC](#)

## 6.8 SO WHAT SORT OF QUESTIONS DOES POLYNOMIAL ARITHMETIC ADDRESS?

- Given two polynomials whose coefficients are derived from a set  $S$ , what can we say about the coefficients of the polynomial that results from an arithmetic operation on the two polynomials?
- If we insist that the polynomial coefficients all come from a particular set  $S$ , then which arithmetic operations are permitted and which prohibited?
- Let's say that the coefficient set is a **finite field**  $F$  with its own rules for addition, subtraction, multiplication, and division, and let's further say that when we carry out an arithmetic operation on two polynomials, we subject the operations on the coefficients to those that apply to the finite field  $F$ . **Now what can be said about the set of such polynomials?** What sort of an algebraic structure would be formed by the set of such polynomials? We take up this question in the next section.

[Back to TOC](#)

## 6.9 POLYNOMIALS OVER A FIELD CONSTITUTE A RING

- For the set of polynomials over a field, we can use polynomial addition as the group operator. **In such additions of the polynomials, we add the coefficients as dictated by the field used for the coefficients.**
- With regard to using polynomial addition as the group operator, the polynomial 0 is obviously the identity element with respect to polynomial addition.
- Polynomial addition is associative and commutative.
- The set of all polynomials over a given field is closed under polynomial addition.
- **Therefore, the set of all polynomials over a field is a legitimate group.**
- We can use polynomial multiplication as the ring operator.

- We can show that polynomial multiplication distributes over polynomial addition.
- We can also show polynomial multiplication is associative.
- Therefore, the set of **all** polynomials over a field constitutes a ring. Such a ring is also called the **polynomial ring**.
- Note the emphasis on “all” in the previous statement. Such a ring is infinite in size since it must contain polynomials of arbitrary degree. Just imagine multiplying the polynomial  $x + 1$  with itself an arbitrary number of times. The only constraint on the polynomials in the ring is that the coefficients of the powers of  $x$  must always belong to the specified finite field.
- Since polynomial multiplication is commutative, the set of polynomials over a field is actually a **commutative ring**.
- In light of the constraints we have placed on what constitutes a polynomial, it does not make sense to talk about multiplicative inverses of polynomials in the set of **all** possible polynomials that can be defined over a finite field. (**Recall that our polynomials do not contain negative powers of  $x$ .**)

- Nevertheless, as you will see in the next lecture, it is possible for a finite set of polynomials, whose coefficients are drawn from a finite field, to constitute a finite field.

[Back to TOC](#)

## 6.10 WHEN IS POLYNOMIAL DIVISION PERMITTED?

- Polynomial division is obviously **not** allowed for polynomials that are **not** defined over fields. For example, for polynomials defined over the set of all integers, you cannot divide  $4x^2 + 5$  by the polynomial  $5x$ . If you tried, the first term of the quotient would be  $(4/5)x$  where the coefficient of  $x$  is not an integer.
- **You can always divide polynomials defined over a field.** That is because the operation of division is **legal** when the coefficients are drawn from a finite field. But note that, in general, when you divide one such polynomial by another, **you will end up with a remainder polynomial**, as is the case when, in general, you divide one integer by another integer in purely integer arithmetic.
- **The bottom line is that you should NOT even think about polynomial division if the coefficients of the powers of  $x$  are NOT drawn from a field.**
- For polynomials defined over a field, the division of a polynomial  $f(x)$  of degree  $m$  by another polynomial  $g(x)$  of

degree  $n \leq m$  can be expressed by

$$\frac{f(x)}{g(x)} = q(x) + \frac{r(x)}{g(x)}$$

where  $q(x)$  is the quotient and  $r(x)$  the remainder.

- So we can write for any two polynomials defined over a field

$$f(x) = q(x)g(x) + r(x)$$

assuming that the degree of  $f(x)$  is not less than that of  $g(x)$ .

- When  $r(x)$  is zero, we say that  $g(x)$  divides  $f(x)$ . This fact can also be expressed by saying that  $g(x)$  is a **divisor** of  $f(x)$  and by the notation  $g(x)|f(x)$ .

[Back to TOC](#)

## 6.11 IRREDUCIBLE POLYNOMIALS, PRIME POLYNOMIALS

- When  $g(x)$  divides  $f(x)$  without leaving a remainder, we say  $g(x)$  is a **factor** of  $f(x)$ .
- A polynomial  $f(x)$  over a field  $F$  is called **irreducible** if  $f(x)$  cannot be expressed as a product of two polynomials, both over  $F$  and both of degree lower than that of  $f(x)$ .
- An irreducible polynomial is also referred to as a **prime polynomial**.

[Back to TOC](#)

## 6.12 HOMEWORK PROBLEMS

1. Where is our main focus in studying polynomial arithmetic:
  - a) in evaluating the value of a polynomial for different values of the variable  $x$  and investigating how the value of the polynomial changes as  $x$  changes;

or

- b) in adding, subtracting, multiplying, and dividing the polynomials and figuring out how to characterize a given set of polynomials with respect to such operations.

2. Divide

$$3x^2 + 4x + 3$$

by

$$5x + 6$$

assuming that the polynomials are over the field  $Z_7$ .

3. Complete the following equalities for the numbers in  $GF(2)$ :

$$1 + 1 = ?$$

$$1 - 1 = ?$$

$$\begin{aligned} -1 &= ? \\ 1 \times 1 &= ? \\ 1 \times -1 &= ? \end{aligned}$$

4. Calculate the result of the following if the polynomials are over  $GF(2)$ :

$$\begin{aligned} (x^4 + x^2 + x + 1) &+ (x^3 + 1) \\ (x^4 + x^2 + x + 1) &- (x^3 + 1) \\ (x^4 + x^2 + x + 1) &\times (x^3 + 1) \\ (x^4 + x^2 + x + 1) &/ (x^3 + 1) \end{aligned}$$

5. When is polynomial division permitted in general?

6. When the coefficients of polynomials are drawn from a finite field, the set of polynomials constitutes a

- a group
- an Abelian group
- a ring
- a commutative ring
- an integral domain

- a field

7. What is an irreducible polynomial?
