filters, map/reduce, and higher order functions
Remove undesired results from a list

Needs two inputs:

- (boolean) function to be carried out
- Iterable (list) to be filtered

```python
li = [5, 7, 22, 97, 54, 62, 77, 23, 73, 61]
final_list = list(filter(lambda x: (x % 2 != 0), li))
print(final_list)
```

The **lambda** function

- Anonymous, i.e., without a name
- Formatted as
  
  lambda arguments: expression

- Can have any number of arguments but only one expression

```python
g = lambda x, y: x + y
print(g(5, 6))
```
map

• Applies a function to all items in an input list (i.e., defines a mapping)

• Needs two inputs:
  • Function to apply
  • Iterable: A sequence, collection, or iterator object

items = [1, 2, 3, 4, 5]
squared = list(map(lambda x: x**2, items))

• Can also map e.g., a list of functions

```python
def multiply(x):
    return (x*x)
def add(x):
    return (x+x)
```

funcs = [multiply, add]
for i in range(5):
    value = list(map(lambda x: x(i), funcs))
    print(value)
**reduce**

- Perform computation on a list and return the (single value) result
- Rolling computation applied to sequential pairs of values
- Needs two inputs:
  - Function to apply
  - Sequence to iterate over

```python
li = [5, 8, 10, 20, 50, 100]
sum = reduce((lambda x, y: x + y), li)
```

- Can also define (non-anonymous) functions
  ```python
def do_sum(x1, x2):
    return x1 + x2
reduce(do_sum, li)
```

- Operator functions can also be used
  ```python
reduce(operator.add, li)
```

- Need to import the relevant modules
  ```python
from functools import reduce
import operator
```
Since functions are treated as first-class objects in Python, they can …

- take one or more functions as arguments

```python
def summation(nums):
    return sum(nums)

def main(f, *args):
    result = f(*args)
    print(result)
```

- return one or more functions

```python
def add_two_nums(x, y):
    return x + y

def add_three_nums(x, y, z):
    return x + y + z

def get_appropriate(num_len):
    if num_len == 3:
        return add_three_nums
    else:
        return add_two_nums
```

- filter, map, and reduce are examples of built-in higher order functions
list comprehension

- Simple way of creating a list based on an iterable
- Elements in the new list are conditionally included and transformed as needed
  
  ```
  [output expression for item in iterable if condition]
  ```
- An example:
  ```python
numbers = [1, 2, 3, 4, 5]
squares = [n**2 for n in numbers if n > 2]
```
- Compared with a for loop
  - More computationally efficient
  - But less flexible!
- Can also have an if-else clause on the output expression
  ```
  [output expression if-else clause for item in iterable condition(s) on iterable]
  ```
- Can use line breaks between brackets for readability
  ```python
numbers = [1, 2, 3, 4, 5, 6, 18, 20]
squares = [
    "small" if number < 10 else "big"
    for number in numbers
    if number % 2 == 0
    if number % 3 == 0
]
```
- Can also be nested
  ```python
l = [['3','4','5'],['6','8','10','12']]
l2 = [[float(y) for y in x] for x in l]
```
