Parsers

Thursday, August 30, 12

Terminology

- Grammar G = (V_t, V_n, S, P)
 - V_t is the set of terminals
 - V_n is the set of non-terminals
 - S is the start symbol
- P is the set of productions
 - Each production takes the form: $V_n \rightarrow \lambda \mid (V_n \mid V_t) +$
 - Grammar is context-free (why?)
- A simple grammar:

 $G = (\{a,b\},\{S,A,B\},\{S \rightarrow A \ B \ \$,A \rightarrow A \ a,A \rightarrow a,B \rightarrow B \ b,B \rightarrow b\},S)$

Thursday, August 30, 12

Agenda

- Terminology
- LL(I) Parsers
- Overview of LR Parsing

Thursday, August 30, 12

Terminology

- V is the vocabulary of a grammar, consisting of terminal (V_t) and non-terminal (V_n) symbols
- For our sample grammar
- $V_n = \{S, A, B\}$
 - Non-terminals are symbols on the LHS of a production
 - Non-terminals are constructs in the language that are recognized during parsing
- $V_t = \{a, b\}$
 - Terminals are the tokens recognized by the scanner
 - They correspond to symbols in the text of the program

Thursday, August 30, 12

Terminology

- Productions (rewrite rules) tell us how to derive strings in the language
 - Apply productions to rewrite strings into other strings
- We will use the standard BNF form
- $P = \{$ $S \rightarrow A B \$$ $A \rightarrow A a$ $A \rightarrow a$ $B \rightarrow B b$ $B \rightarrow b$

Generating strings

 $S \rightarrow A B$ \$

 $A \rightarrow A a$

 $A \rightarrow a$

 $B \rightarrow B b$

 $B \rightarrow b$

- Given a start rule, productions tell us how to rewrite a non-terminal into a different set of symbols
- By convention, first production applied has the start symbol on the left, and there is only one such production

To derive the string "a a b b b" we can do the following rewrites:

```
S \Rightarrow A B \$ \Rightarrow A a B \$ \Rightarrow a a B b \$ \Rightarrow a a B b \$ \Rightarrow a a B b b \$ \Rightarrow a a b b b \$
```

Thursday, August 30, 12

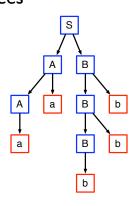

Terminology

- Strings are composed of symbols
 - AAaaBbbAais a string
 - We will use Greek letters to represent strings composed of both terminals and non-terminals
- L(G) is the language produced by the grammar G
 - All strings consisting of only terminals that can be produced by G
 - In our example, L(G) = a+b+\$
 - All regular expressions can be expressed as grammars for context-free languages, but not vice-versa
 - Consider: ai bi \$ (what is the grammar for this?)

Thursday, August 30, 12

Parse trees

- Tree which shows how a string was produced by a language
 - Interior nodes of tree: nonterminals
 - Children: the terminals and non-terminals generated by applying a production rule
 - Leaf nodes: terminals

Thursday, August 30, 12

Leftmost derivation

- Rewriting of a given string starts with the leftmost symbol
- Exercise: do a leftmost derivation of the input program

$$F(V + V)$$

using the following grammar:

| E | \rightarrow | Prefix (E) |
|--------|---------------|------------|
| E | \rightarrow | V Tail |
| Prefix | → | F |
| Prefix | → | λ |
| Tail | → | + E |
| Tail | → | λ |

• What does the parse tree look like?

Thursday, August 30, 12

Rightmost derivation

- Rewrite using the rightmost non-terminal, instead of the left
- What is the rightmost derivation of this string?

$$F(V + V)$$

| E | \rightarrow | Prefix (E) |
|--------|---------------|------------|
| E | \rightarrow | V Tail |
| Prefix | \rightarrow | F |
| Prefix | → | λ |
| Tail | → | + E |
| Tail | → | λ |

Thursday, August 30, 12

Simple conversions

 $A \rightarrow B$ $A \rightarrow C$

D → E Ftail Ftail → F Ftail Ftail → λ

Thursday, August 30, 12

Top-down vs. Bottom-up parsers

- Top-down parsers expand the parse tree in pre-order
 - Identify parent nodes before the children
- Bottom-up parsers expand the parse tree in post-order
 - Identify children before the parents
- Notation:
 - LL(1):Top-down derivation with 1 symbol lookahead
 - LL(k):Top-down derivation with k symbols lookahead
 - LR(I): Bottom-up derivation with I symbol lookahead

What is parsing

- Parsing is recognizing members in a language specified/ defined/generated by a grammar
- When a construct (corresponding to a production in a grammar) is recognized, a typical parser will take some action
 - In a compiler, this action generates an intermediate representation of the program construct
 - In an interpreter, this action might be to perform the action specified by the construct. Thus, if a+b is recognized, the value of a and b would be added and placed in a temporary variable

Thursday, August 30, 12

Top-down parsing

Thursday, August 30, 12

Top-down parsing

- Idea: we know sentence has to start with initial symbol
- Build up partial derivations by <u>predicting</u> what rules are used to expand non-terminals
- Often called predictive parsers
- If partial derivation has terminal characters, match them from the input stream

Thursday, August 30, 12

A simple example

 $S \rightarrow A B c$ \$

 $A \rightarrow x a A$

 $A \rightarrow y a A$

 $A \rightarrow c$

 $B \rightarrow b$ • A sentence in the grammar:

 $B \to \lambda \hspace{1cm} x \, a \, c \, c \, \$$

Thursday, August 30, 12

A simple example

 $S \rightarrow A B c$ \$

 $A \rightarrow x a A$

 $\mathsf{A} \to \mathsf{y} \, \mathsf{a} \, \mathsf{A}$

 $A \rightarrow c$

 $B \rightarrow b$ • A sentence in the grammar:

 $B \rightarrow \lambda$ x a c c \$

Current derivation: S

A simple example

 $S \rightarrow A B c$ \$

 $A \rightarrow x a A$

 $A \rightarrow y a A$

 $A \rightarrow c$

 $B \rightarrow b$ • A sentence in the grammar:

 $B \rightarrow \lambda$ x a c c \$

Current derivation: A B c \$

Predict rule

 $S \rightarrow A B c$ \$

Choose based on first set of rules

 $B \rightarrow b$

• A sentence in the grammar:

 $B \rightarrow \lambda$

xacc\$

Current derivation: x a A B c \$

Predict rule based on next token

Thursday, August 30, 12

A simple example

 $S \rightarrow A B c$ \$

 $A \rightarrow x a A$

 $A \rightarrow y a A$

 $A \rightarrow c$

 $B \rightarrow b$ • A sentence in the grammar:

 $B \rightarrow \lambda$

xacc\$

Current derivation: x a A B c \$

Match token

Thursday, August 30, 12

A simple example

 $S \rightarrow A B c$ \$

 $A \rightarrow x a A$

 $A \rightarrow y a A$

 $A \rightarrow c$

 $B \rightarrow b$ • A sentence in the grammar:

 $B \rightarrow \lambda$ xacc\$

Current derivation: x a A B c \$

Match token

Thursday, August 30, 12

A simple example

 $S \rightarrow A B c$ \$

Choose based on first set of rules

 $A \rightarrow x a A$ $A \rightarrow y a A$ $A \rightarrow c$

 $B \rightarrow b$

• A sentence in the grammar:

 $B \rightarrow \lambda$ x a c c \$

Current derivation: x a c B c \$

Predict rule based on next token

Thursday, August 30, 12

A simple example

 $S \rightarrow A B c$ \$

 $A \rightarrow x a A$

 $A \rightarrow y a A$ $A \rightarrow c$

 $B \rightarrow b$ • A sentence in the grammar:

 $B \rightarrow \lambda$ x a c c \$

Current derivation: x a c B c \$

Match token

Thursday, August 30, 12

A simple example

 $S \rightarrow A B c$ \$

 $A \rightarrow x a A$

Choose based on follow set

 $A \rightarrow y a A$

 $\mathsf{A} \to \mathsf{c}$

 $B \rightarrow b$

A sentence in the grammar:

B → λ xacc\$

Current derivation: \times a c λ c \$

Predict rule based on next token

A simple example

 $S \rightarrow A B c$ \$

 $A \rightarrow x a A$

 $A \rightarrow y a A$

 $A \rightarrow c$

 $B \rightarrow b$ • A sentence in the grammar:

 $B \rightarrow \lambda$ xacc\$

Current derivation: x a c c \$

Match token

Thursday, August 30, 12

Thursday, August 30, 12

A simple example

 $S \rightarrow A B c$ \$

 $A \rightarrow x a A$

 $A \rightarrow y a A$

 $A \rightarrow c$

• A sentence in the grammar:

 $B \rightarrow \lambda$ xacc\$

Current derivation: x a c c \$

Match token

First and follow sets

Follow(A) = $\{a \in V_t \mid S \Rightarrow^+ ... Aa ...\} \cup \{\$ \mid \text{if } S \Rightarrow^+ ... A \$\}$

 $\bullet \quad \mathsf{First}(\alpha) = \{ a \in \mathsf{V}_t \mid \alpha \Rightarrow^* a\beta \} \cup \{ \lambda \mid \mathsf{if} \ \alpha \Rightarrow^* \lambda \}$

Thursday, August 30, 12

First and follow sets

First(α): the set of terminals that begin all strings that can be derived from α

• First(A) = {x, y}

 $S \rightarrow A B$ \$ $A \rightarrow x a A$

 $A \rightarrow \lambda$

 $B \rightarrow b$

• First(xaA) = {x}

 $A \rightarrow y a A$

• First (AB) = {x, y, b}

• Follow(A): the set of terminals that can appear immediately after A in some partial derivation

a non-terminal symbol α,β : a string composed of terminals and non-terminals (typically, α is the

• Follow(A) = {b}

RHS of a production

start symbol

a terminal symbol

derived in I step

derived in 0 or more steps

derived in 1 or more steps

Thursday, August 30, 12

Computing first sets

- Terminal: First(a) = {a}
- Non-terminal: First(A)
 - Look at all productions for A

$$A \rightarrow X_1 X_2 ... X_k$$

- First(A) \supseteq (First(X_I) λ)
- $\bullet \quad \text{If } \lambda \in \text{First}(X_1), \text{First}(A) \supseteq (\text{First}(X_2) \lambda)$
- If λ is in First(X_i) for all i, then $\lambda \in First(A)$
- Computing First(α): similar procedure to computing First(A)

Exercise

What are the first sets for all the non-terminals in following grammar:

 $S \rightarrow A B$ \$

 $A \rightarrow x a A$

 $A \rightarrow y a A$

 $A \rightarrow \lambda$

 $B \rightarrow b$

 $B \rightarrow A$

Thursday, August 30, 12

Computing follow sets

- Follow(S) = {}
- To compute Follow(A):
 - Find productions which have A on rhs. Three rules:

1. $X \rightarrow \alpha A \beta$: Follow(A) \supseteq (First(β) - λ)

2. $X \to \alpha A \beta$: If $\lambda \in First(\beta)$, $Follow(A) \supseteq Follow(X)$

3. $X \rightarrow \alpha A$: Follow(A) \supseteq Follow(X)

• Note: Follow(X) never has λ in it.

Thursday, August 30, 12

Exercise

• What are the follow sets for

 $S \rightarrow A B$ \$

 $A \rightarrow x a A$

 $A \rightarrow yaA$

 $A \rightarrow \lambda$

 $B \rightarrow b$

 $B \rightarrow A$

Thursday, August 30, 12

Towards parser generators

- Key problem: as we read the source program, we need to decide what productions to use
- Step I: find the tokens that can tell which production P (of the form A $\to X_1 X_2 \dots X_m$) applies

Predict(P) =

$$\left\{ \begin{array}{ll} \operatorname{First}(X_1 \dots X_m) & \text{if } \lambda \not \in \operatorname{First}(X_1 \dots X_m) \\ \left(\operatorname{First}(X_1 \dots X_m) - \lambda\right) \cup \operatorname{Follow}(A) & \text{otherwise} \end{array} \right.$$

 If next token is in Predict(P), then we should choose this production

Thursday, August 30, 12

Parse tables

- Step 2: build a parse table
 - Given some non-terminal V_n (the non-terminal we are currently processing) and a terminal V_t (the lookahead symbol), the parse table tells us which production P to use (or that we have an error
 - More formally:

 $T{:}V_n \times V_t \to P \cup \{Error\}$

Thursday, August 30, 12

Building the parse table

 Start:T[A][t] = //initialize all fields to "error" foreach A:

foreach P with A on its Ihs:

foreach t in Predict(P):

• Exercise: build parse table for our toy grammar

__...

T[A][t] = P

 $I.S \rightarrow AB$ \$

 $2.A \rightarrow \times aA$ $3.A \rightarrow y a A$

4. A → λ

 $5.B \rightarrow b$

Stack-based parser for LL(I)

- Given the parse table, a stack-based algorithm is much simpler to generate than a recursive descent parser
- Basic algorithm:
 - I. Push the RHS of a production onto the stack
 - 2. Pop a symbol, if it is a terminal, match it
 - 3. If it is a non-terminal, take its production according to the parse table and go to I
- Algorithm on page 121
- Note: always start with start state

Thursday, August 30, 12

An example

I. $S \rightarrow AB$ \$ 2. $A \rightarrow x a A$

• How would a stack-based parser parse:

3. A → y a A 4. A → λ

xayab

5. B → b

| Parse stack | Remaining input | Parser action |
|-------------|-----------------|---------------|
| S | xayab\$ | predict I |

Thursday, August 30, 12

| A B \$ | b \$ | predict 4 |
| В\$ | b \$ | predict 5 |
| b \$ | b \$ | match(b) |
| \$ | \$ | Done! |

Thursday, August 30, 12

Dealing with semantic actions

- When a construct (corresponding to a production in a grammar) is recognized, a typical parser will invoke a semantic action
 - In a compiler, this action generates an intermediate representation of the program construct
- In an interpreter, this action might be to perform the action specified by the construct. Thus, if a+b is recognized, the value of a and b would be added and placed in a temporary variable

Dealing with semantic actions

- We can annotate a grammar with action symbols
 - Tell the parser to invoke a semantic action routine
- Can simply push action symbols onto stack as well
- When popped, the semantic action routine is called
 - Routine manipulates semantic records on a stack
 - Can generate new records (e.g., to store variable info)
 - Can generate code using existing records
- Example: semantic actions for x = a + 3

statement ::= ID #id = expr #assign expr ::= term + term #addop term ::= ID #id | LITERAL #num

Thursday, August 30, 12

Non-LL(I) grammars

- Not all grammars are LL(I)!
- Consider

<stmt> → if <expr> then <stmt list> endif

<stmt> → if <expr> then <stmt list> else <stmt list> endif

- This is not LL(I) (why?)
- We can turn this in to

<stmt> → if <expr> then <stmt list> <if suffix>

<if suffix> → endif

<if suffix> → else <stmt list> endif

Thursday, August 30, 12

Left recursion

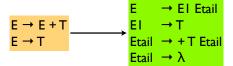

- Left recursion is a problem for LL(1) parsers
 - LHS is also the first symbol of the RHS
- Consider:

 $E \rightarrow E + T$

• What would happen with the stack-based algorithm?

Thursday, August 30, 12

Removing left recursion

Thursday, August 30, 12

LL(k) parsers

- Can look ahead more than one symbol at a time
 - k-symbol lookahead requires extending first and follow sets
 - 2-symbol lookahead can distinguish between more rules:

$$A \rightarrow ax \mid ay$$

- More lookahead leads to more powerful parsers
- What are the downsides?

Are all grammars LL(k)?

• No! Consider the following grammar:

 $S \rightarrow E$ $E \rightarrow (E + E)$ $E \rightarrow (E - E)$

- When parsing E, how do we know whether to use rule 2 or 3?
 - Potentially unbounded number of characters before the distinguishing '+' or '-' is found
 - No amount of lookahead will help!

In real languages?

- Consider the if-then-else problem
- if x then y else z
- Problem: else is optional
- if a then if b then c else d
 - Which if does the else belong to?
- This is analogous to a "bracket language": $[i \]^j$ ($i \ge j$)

$$\begin{array}{lll} S & \rightarrow [S C \\ S & \rightarrow \lambda \\ C & \rightarrow] & [[] can be parsed: SS \lambda C or SS C \lambda \\ C & \rightarrow \lambda & \\ \end{array}$$

Thursday, August 30, 12

Solving the if-then-else problem

- The ambiguity exists at the language level. To fix, we need to define the semantics properly
 - "] matches nearest unmatched ["
 - This is the rule C uses for if-then-else
 - What if we try this?

 $S \rightarrow [S \\ S \rightarrow SI \\ SI \rightarrow [SI]$ $SI \rightarrow \lambda$

This grammar is still not LL(I) (or LL(k) for any k!)

Thursday, August 30, 12

Two possible fixes

- If there is an ambiguity, prioritize one production over another
 - e.g., if C is on the stack, always match "]" before matching "λ"

 $\begin{array}{ccc} S & \rightarrow [SC \\ S & \rightarrow \lambda \\ C & \rightarrow] \end{array}$

- Another option: change the language!
 - e.g., all if-statements need to be closed with an endif

 $S \rightarrow if S E$ $S \rightarrow other$ $E \rightarrow else S endif$ $E \rightarrow endif$

Thursday, August 30, 12

Parsing if-then-else

- What if we don't want to change the language?
 - C does not require { } to delimit single-statement blocks
- To parse if-then-else, we need to be able to look ahead at the entire rhs of a production before deciding which production to use
 - In other words, we need to determine how many "]" to match before we start matching "["s
- LR parsers can do this!

Thursday, August 30, 12

LR Parsers

- Parser which does a Left-to-right, Right-most derivation
 - Rather than parse top-down, like LL parsers do, parse bottom-up, starting from leaves
- Basic idea: put tokens on a stack until an entire production is found.
- Issues:
 - Recognizing the endpoint of a production
 - Finding the length of a production (RHS)
 - Finding the corresponding nonterminal (the LHS of the production)

LR Parsers

- Basic idea:
 - shift tokens onto the stack. At any step, keep the set of productions that could generate the read-in tokens
 - reduce the RHS of recognized productions to the corresponding non-terminal on the LHS of the production. Replace the RHS tokens on the stack with the LHS non-terminal.

Data structures

- At each state, given the next token,
 - A goto table defines the successor state
 - An action table defines whether to
 - shift put the next state and token on the stack
 - reduce an RHS is found; process the production
 - terminate parsing is complete

Thursday, August 30, 12

Simple example

I. $P \rightarrow S$

2. $S \rightarrow x; S$

3. $S \rightarrow e$

| | Symbol | | | | | | |
|-------|--------|---|---|---|---|---|----------|
| | | х | ; | e | Р | S | Action |
| | 0 | - | | 3 | | 5 | Shift |
| | ı | | 2 | | | | Shift |
| State | 2 | _ | | 3 | | 4 | Shift |
| State | 3 | | | | | | Reduce 3 |
| | 4 | | | | | | Reduce 2 |
| | 5 | | | | | | Accept |

Thursday, August 30, 12

Parsing using an LR(0) parser

- Basic idea: parser keeps track, simultaneously, of all possible productions that could be matched given what it's seen so far.
 When it sees a full production, match it.
- Maintain a parse stack that tells you what state you're in
 - Start in state 0
- In each state, look up in action table whether to:
 - shift: consume a token off the input; look for next state in goto table; push next state onto stack
 - reduce: match a production; pop off as many symbols from state stack as seen in production; look up where to go according to non-terminal we just matched; push next state onto stack
 - accept: terminate parse

Thursday, August 30, 12

Example

Parse "x;x;e"

| Step | Parse Stack Remaining Input | | Parser Action | |
|------|-----------------------------|---------------|-------------------|--|
| 1 | 0 | x;x;e | Shift I | |
| 2 | 0 1 | ; x ; e | Shift 2 | |
| 3 | 0 2 | x;e | Shift I | |
| 4 | 0 2 | ; e | Shift 2 | |
| 5 | 0 2 2 | e | Shift 3 | |
| 6 | 0 2 2 3 | | Reduce 3 (goto 4) | |
| 7 | 0 2 2 4 | | Reduce 2 (goto 4) | |
| 8 | 0 1 2 4 | Reduce 2 (got | | |
| 9 | 0.5 | Accept | | |

Thursday, August 30, 12

LR(k) parsers

- LR(0) parsers
 - No lookahead
 - Predict which action to take by looking only at the symbols currently on the stack
- LR(k) parsers
 - Can look ahead k symbols
 - Most powerful class of deterministic bottom-up parsers
 - LR(I) and variants are the most common parsers

Terminology for LR parsers

Configuration: a production augmented with a "•"

$$A \rightarrow X_1 \dots X_i \cdot X_{i+1} \dots X_j$$

- The "•" marks the point to which the production has been recognized. In this case, we have recognized $X_1 \dots X_i$
- Configuration set: all the configurations that can apply at a given point during the parse:

 $A \rightarrow B \cdot CD$

 $A \rightarrow B \cdot GH$

 $T \rightarrow B \cdot Z$

 Idea: every configuration in a configuration set is a production that we could be in the process of matching

Configuration closure set

- Include all the configurations necessary to recognize the next symbol after the •
- For each configuration in set:
 - If next symbol is terminal, no new configuration added
 - If next symbol is non-terminal X, for each production of the form $X \to \alpha$, add configuration $X \to {}^\bullet\alpha$

closure0($\{S \rightarrow \cdot E \$\}$) = $\{S \rightarrow \cdot E \$\}$ $E \rightarrow \cdot E + T$ $E \rightarrow \cdot T$ $T \rightarrow \cdot |D$ $T \rightarrow \cdot (E)$

Thursday, August 30, 12

Successor configuration set

• Starting with the initial configuration set

 $s0 = closure0(\{S \rightarrow \bullet \alpha \$\})$

an LR(0) parser will find the successor given the next symbol \boldsymbol{x}

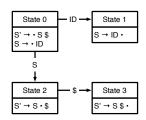

- X can be either a terminal (the next token from the scanner) or a non-terminal (the result of applying a reduction)
- Determining the successor s' = go_to0(s, X):
 - For each configuration in s of the form A \to β X γ add A \to β X γ to t
 - s' = closure0(t)

Thursday, August 30, 12

CFSM

- CFSM = Characteristic Finite State Machine
- Nodes are configuration sets (starting from s0)
- Arcs are go_to relationships

Thursday, August 30, 12

Building the goto table

We can just read this off from the CFSM

| | | | Symbol | |
|-------|-----|----|--------|---|
| | | ID | \$ | S |
| State | 0 | I | | 2 |
| | - 1 | | | |
| | 2 | | 3 | |
| | 3 | | | |

Thursday, August 30, 12

Building the action table

- Given the configuration set s:
 - We shift if the next token matches a terminal after the in some configuration

 $A \rightarrow \alpha \bullet a \ \beta \in \underline{s} \ and \ a \in V_t,$ else error

• We reduce production P if the • is at the end of a production

 $B \to \alpha \bullet \in s$ where production P is $B \to \alpha$

- Extra actions:
 - shift if goto table transitions between states on a nonterminal
 - accept if we have matched the goal production

Action table

| | 0 | Shift |
|-------|---|----------|
| State | - | Reduce 2 |
| | 2 | Shift |
| | 3 | Accept |

Conflicts in action table

- For LR(0) grammars, the action table entries are unique: from each state, can only shift or reduce
- But other grammars may have conflicts
 - Reduce/reduce conflicts: multiple reductions possible from the given configuration
 - Shift/reduce conflicts: we can either shift or reduce from the given configuration

Thursday, August 30, 12

Shift/reduce conflict

• Consider the following grammar:

 $S \rightarrow A y$

 $A \rightarrow x \mid xx$

 This leads to the following configuration set (after shifting one "x":

 $A \rightarrow x \cdot x$

 $A \rightarrow x$

Can shift or reduce here

Thursday, August 30, 12

Shift/reduce example (2)

• Consider the following grammar:

 $S \rightarrow A y$

 $A \rightarrow \lambda \mid x$

• This leads to the following initial configuration set:

 $S \rightarrow \bullet A y$

 $A \rightarrow \bullet x$

 $\mathsf{A} \to \lambda \, \bullet$

• Can shift or reduce here

Thursday, August 30, 12

Lookahead

- Can resolve reduce/reduce conflicts and shift/reduce conflicts by employing lookahead
 - Looking ahead one (or more) tokens allows us to determine whether to shift or reduce
 - (cf how we resolved ambiguity in LL(I) parsers by looking ahead one token)

Thursday, August 30, 12

Semantic actions

- Recall: in LL parsers, we could integrate the semantic actions with the parser
 - Why? Because the parser was predictive
- Why doesn't that work for LR parsers?
 - Don't know which production is matched until parser reduces
- For LR parsers, we put semantic actions at the end of productions
 - May have to rewrite grammar to support all necessary semantic actions

Parsers with lookahead

- Adding lookahead creates an LR(I) parser
- Built using similar techniques as LR(0) parsers, but uses lookahead to distinguish states
- LR(1) machines can be much larger than LR(0) machines, but resolve many shift/reduce and reduce/ reduce conflicts
- Other types of LR parsers are SLR(I) and LALR(I)
 - Differ in how they resolve ambiguities
 - yacc and bison produce LALR(I) parsers

Thursday, August 30, 12

LR(I) parsing

 Configurations in LR(I) look similar to LR(0), but they are extended to include a lookahead symbol

$$A \xrightarrow{} X_1 \dots X_i \xrightarrow{\bullet} X_{i+1} \dots X_j$$
 , I (where $I \in V_t \cup \lambda)$

 If two configurations differ only in their lookahead component, we combine them

$$\mathsf{A} \to \mathsf{X}_1 \dots \mathsf{X}_i \bullet \mathsf{X}_{i+1} \dots \mathsf{X}_j \ , \{I_1 \dots I_m\}$$

Thursday, August 30, 12

Building configuration sets

To close a configuration

$$B \rightarrow \alpha \cdot A \beta, I$$

- Add all configurations of the form A → γ, u where u ∈ First(βI)
- Intuition: the lookahead symbol for any configuration is the terminal we expect to see after the configuration has been matched
 - The parse could apply the production for A, and the lookahead after we apply the production should match the next token that would be produced by B

Thursday, August 30, 12

Example

closure I ($\{S \rightarrow \bullet E \$, \{\lambda\}\}$) =

Thursday, August 30, 12

Example

closure I ({S \rightarrow • E \$, { λ }}) = S \rightarrow • E \$, { λ }

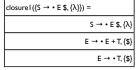

Thursday, August 30, 12

Example

Example

 $S \rightarrow E \$ $E \rightarrow E + T \$ $T \rightarrow ID \ | \ (E)$

Example

| closure I ($\{S \rightarrow \bullet E \$, \{\lambda\}\}$) | = |
|---|------------------|
| | S → • E \$, {λ |
| | E → • E + T, {\$ |
| | E → • T, {\$ |
| | T → • ID, {\$ |

Thursday, August 30, 12

Example

| closure I ($\{S \rightarrow \bullet E \$, \{\lambda\}\}$ | }) = |
|---|-------------------|
| | S → • E \$, {λ} |
| | E → • E + T, {\$} |
| | E → • T, {\$} |
| | T → • ID, {\$} |
| | T → • (E), {\$} |

Thursday, August 30, 1

Example

| closure I ($\{S \rightarrow \bullet E \$, \{\lambda\}\}$ | \}}) = |
|---|-------------------|
| | S → • E \$, {λ} |
| | E → • E + T, {\$} |
| | E → • T, {\$} |
| | T → • ID, {\$} |
| | T → • (E), {\$} |
| | E → • E + T, {+} |

Thursday, August 30, 12

Example

| closure I ($\{S \rightarrow \bullet E \$, \{\lambda\}\}$ | }}) = |
|---|---|
| | $S \rightarrow \bullet E \$, \{\lambda\}$ |
| | E → • E + T, {\$} |
| | E → • T, {\$} |
| | T → • ID, {\$} |
| | T → • (E), {\$} |
| | E → • E + T, {+} |

| | E → • T, {+} |
| | T → • ID, {+} |
| | T → • (E), {+} |
| | |

Building goto and action tables

- The function gotol (configuration-set, symbol) is analogous to gotol(configuration-set, symbol) for LR(0)
 - Build goto table in the same way as for LR(0)
- Key difference: the action table.

action[s][x] =

• reduce when • is at end of configuration and $x \in lookahead$ set of configuration

$$A \, \rightarrow \, \alpha \, \bullet, \{... \, x \, ...\} \in s$$

• shift when • is before x

$$A \to \beta \bullet x \ \gamma \in s$$

Thursday, August 30, 12

Example

• Consider the simple grammar:

<stmts> → begin <stmts> end ; <stmts>

 $\langle stmts \rangle \rightarrow \lambda$

Thursday, August 30, 12

Action and goto tables

| | begin | end | ; | SimpleStmt | \$ | <pre><pre><pre><pre>program></pre></pre></pre></pre> | <stmts></stmts> |
|-----|-------|--------|-------|------------|----|---|-----------------|
| 0 | S/I | | | | | | |
| 1 | S / 4 | R4 | | \$ / 5 | | | S / 2 |
| 2 | | S / 3 | | | | | |
| 3 | | | | | Α | | |
| 4 | S / 4 | R4 | | \$ / 5 | | | S / 7 |
| 5 | | | S / 6 | | | | |
| 6 | S / 4 | R4 | | \$ / 5 | | | S / 10 |
| 7 | | \$ / 8 | | | | | |
| 8 | | | \$/9 | | | | |
| 9 | S / 4 | R4 | | \$ / 6 | | | S / II |
| 10 | | R2 | | | | | |
| -11 | | R3 | | | | | · |

Thursday, August 30, 12

Parse: begin SimpleStmt; SimpleStmt; end \$

| Step | Parse Stack | Remaining Input | Parser Action |
|------|----------------|-----------------|--------------------|
| I | 0 | begin S;S;end\$ | Shift I |
| 2 | 0 1 | S;S;end \$ | Shift 5 |
| 3 | 0 5 | ; S ; end \$ | Shift 6 |
| 4 | 0 5 6 | S ; end \$ | Shift 5 |
| 5 | 0 5 6 5 | ; end \$ | Shift 6 |
| 6 | 0 5 6 5 6 | end \$ | Reduce 4 (goto 10) |
| 7 | 0 1 5 6 5 6 10 | end \$ | Reduce 2 (goto 10) |
| 8 | 0 1 5 6 10 | end \$ | Reduce 2 (goto 2) |
| 9 | 0 2 | end \$ | Shift 3 |
| 10 | 0 2 3 | \$ | Accept |

Thursday, August 30, 12

Problems with LR(I) parsers

- LR(I) parsers are very powerful ...
 - But the table size is much larger than LR(0) as much as a factor of $|V_t|$ (why?)
 - Example: Algol 60 (a simple language) includes several thousand states!
- Storage efficient representations of tables are an important issue.

Solutions to the size problem

- Different parser schemes
- SLR (simple LR): build an CFSM for a language, then add lookahead wherever necessary (i.e., add lookahead to resolve shift/reduce conflicts)
 - What should the lookahead symbol be?
 - To decide whether to reduce using production A → α, use Follow(A)
- LALR: merge LR states in certain cases (we won't discuss this)
