Introduction to Prestressing CE 572

Purdue University School of Civil Engineering

Julio Ramirez

Definition of Prestressing

It consists of preloading the structure before application of design loads in such a way so as to improve its general performance.

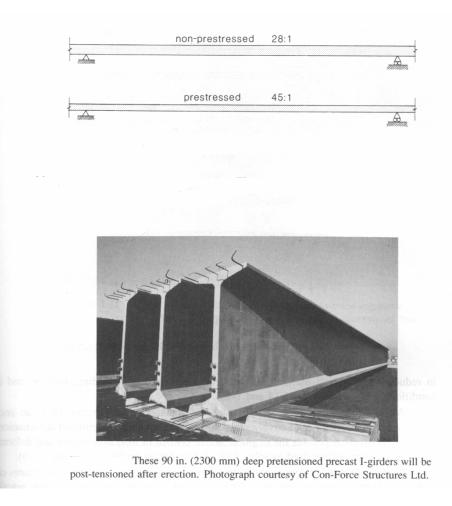

Objectives of Prestressing

- Control or eliminate tensile stresses in the concrete (cracking) at least up to service load levels.
- Control or eliminate deflection at some specific load level.
- Allow the use of high strength steel and concrete.

Net Result of Prestressing

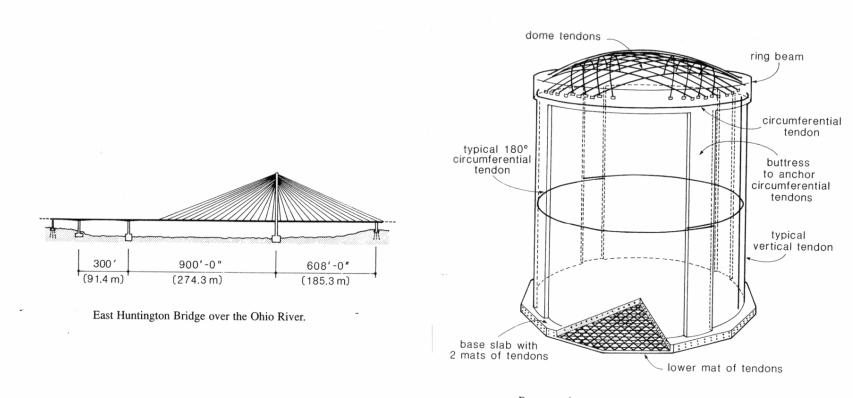

- Improved performance of concrete in "ordinary" design situations (compared to R/C).
- Extended range of application of structural concrete (longer spans).
- Innovative forms of structures.

Extended Range of Application

CE572/Spring 04/JAR

Examples of Structures

Prestressed concrete containment structure for nuclear power plant.

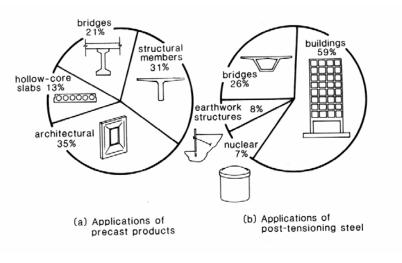

CE572/Spring 04/JAR

Partial Prestressing

- Intermediate state, in which tension and usually flexure cracking is allowed at full service load level. Some advantages are:
 - Prevents excessive camber at more typical loads less than full service loads.
 - Reduced prestressing force (less \$\$\$) compared to full prestressing (zero tensile stresses at full service load).

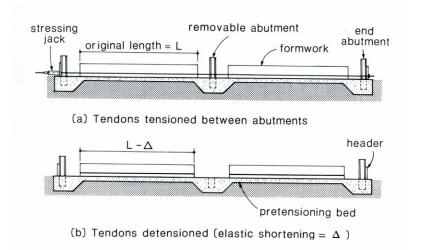

Applications of Prestressed Concrete in the US and Canada – Figure 1

About 200,000 tons of prestressing steel used in US/Canada each year (~ ¼ of the total world consumption)

Prestressing Methods

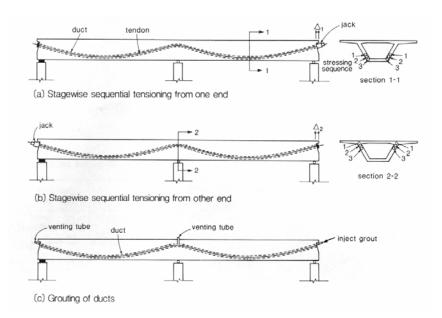

Pretensioning: suited for mass production.

*Video (PCI)

Prestressing Methods

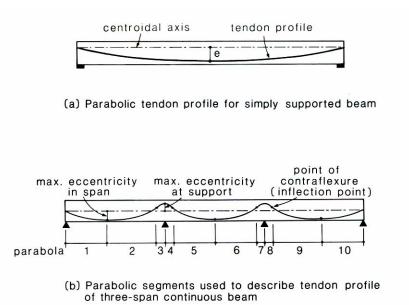

Post-Tensioning: jacking against the member and the eccentricity is easily varied along the length of the member.

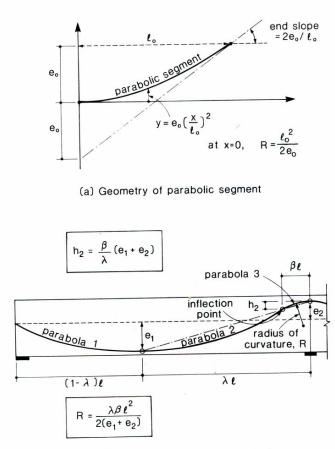

Post-Tensioning Sequence

- Place reinforcing cage and post-tensioning ducts inside the formwork.
- After casting and curing of the concrete, the tendons are tensioned and anchored with special jacks that react against the member.
- Unless unbonded tendons are being used, the duct is then grouted to complete the post-tensioning operation.
- Slides (PTI)------

Profiles of Post-Tensioned Tendons

Hognestad Parabola

$$fc(\varepsilon) := \left[fcmax \cdot \left[\left(2 \cdot \frac{\varepsilon}{\varepsilon 0} \right) - \left(\frac{\varepsilon}{\varepsilon 0} \right)^2 \right] \right] \qquad Ec := 57000 \frac{\sqrt[2]{(fcmax)}}{1000}$$

Calculate ε_o (strain corresponding to peak stress, fcmax) using the secant Modulus of Elasticity at 0.5fcmax. Thus, fit The Hognestad expression through a point corresponding to 0.5fcmax and 0.5fcmax/Ec.
