

It rains during the construction of a building and water fills a recently excavated pit to a depth, $h=0.5\text{m}$. In order to continue construction, the water must first be pumped out of the pit. A hose with a length of $L=50\text{m}$, a diameter of $D=2.5\cdot 10^{-2}\text{m}$, and a surface roughness of $\varepsilon=5.0\cdot 10^{-5}\text{m}$ is attached to a pump. Note that the kinematic viscosity of the water is $\nu=1.005\cdot 10^{-6}\text{ m}^2/\text{s}$ and the density is $\rho=1000\text{ kg}/\text{m}^3$.

- If the pump is placed at the pit's surface (figure a), what is the maximum depth of the pit, H , for which water can be pumped out at a velocity of $V=1\text{ m/s}$ without causing cavitation in the pipe? The vapor pressure of water for the current temperature is $p_v=2.337\text{ kPa}$ (absolute pressure) and atmospheric pressure is $p_{\text{atm}}=101\text{ kPa}$ (absolute pressure).
- If the pump is placed at the bottom of the pit (figure b), what is the maximum depth of the pit, H , for which water can be pumped out at a velocity of $V=1\text{ m/s}$? Assume that the pump supplies a power of $P=200\text{ W}$ to the fluid.
