

6. Forces on Objects Immersed in a Fluid Flow

The force acting on an object immersed in a fluid flow is comprised of the force due to pressure variations over the surface and the force due to viscous shear stresses.

If we know the pressure (p) and shear stress (τ) distribution over the object, then:

$$\mathbf{F}_p = \int_A -p \hat{\mathbf{n}} dA$$

$$\mathbf{F}_{S,i} = \int_A \tau_{ji} n_j dA$$

where \mathbf{F}_p is the force due to the pressure component, \mathbf{F}_s is the force due to the shear stress component, and A is the surface area of the object.

The component of the force acting in the direction parallel to the incoming flow is known as the drag force, F_{D_x} and the component perpendicular to the incoming flow is known as the lift force, F_{L_y} .

Notes:

1. The pressure force component of the drag is known as form drag while the shear stress drag component is known as the skin friction drag.
2. A streamlined body is one in which the (skin friction drag) \gg (form drag).

A bluff body is one in which the (form drag) \gg (skin friction drag).

3. The lift and drag are often expressed in dimensionless form as a lift and drag coefficient, C_D and C_L :

$$C_L = \frac{F_L}{\frac{1}{2} \rho U_\infty^2 A} \quad C_D = \frac{F_D}{\frac{1}{2} \rho U_\infty^2 A}$$

where A is usually the frontal projected area (area seen from the front) for a bluff body or the planform area (the area seen from above) for a streamlined body.

bluff body
(use the frontal projected area)

streamlined body
(use the planform area)

Flow Around a Cylinder (or Sphere) As a Function of Reynolds Number

Note: $Re = \frac{VD}{\nu}$

$Re \ll 1$
(creeping or Stoke's flow)

$5 < Re < 50$
(fixed eddies)

$60 < Re < 5000$
(Karman Vortex Street,
periodic shedding of vortices)

$5000 < Re < 200,000$

$Re \approx 200,000$
(drag crisis)

$Re > 200,000$

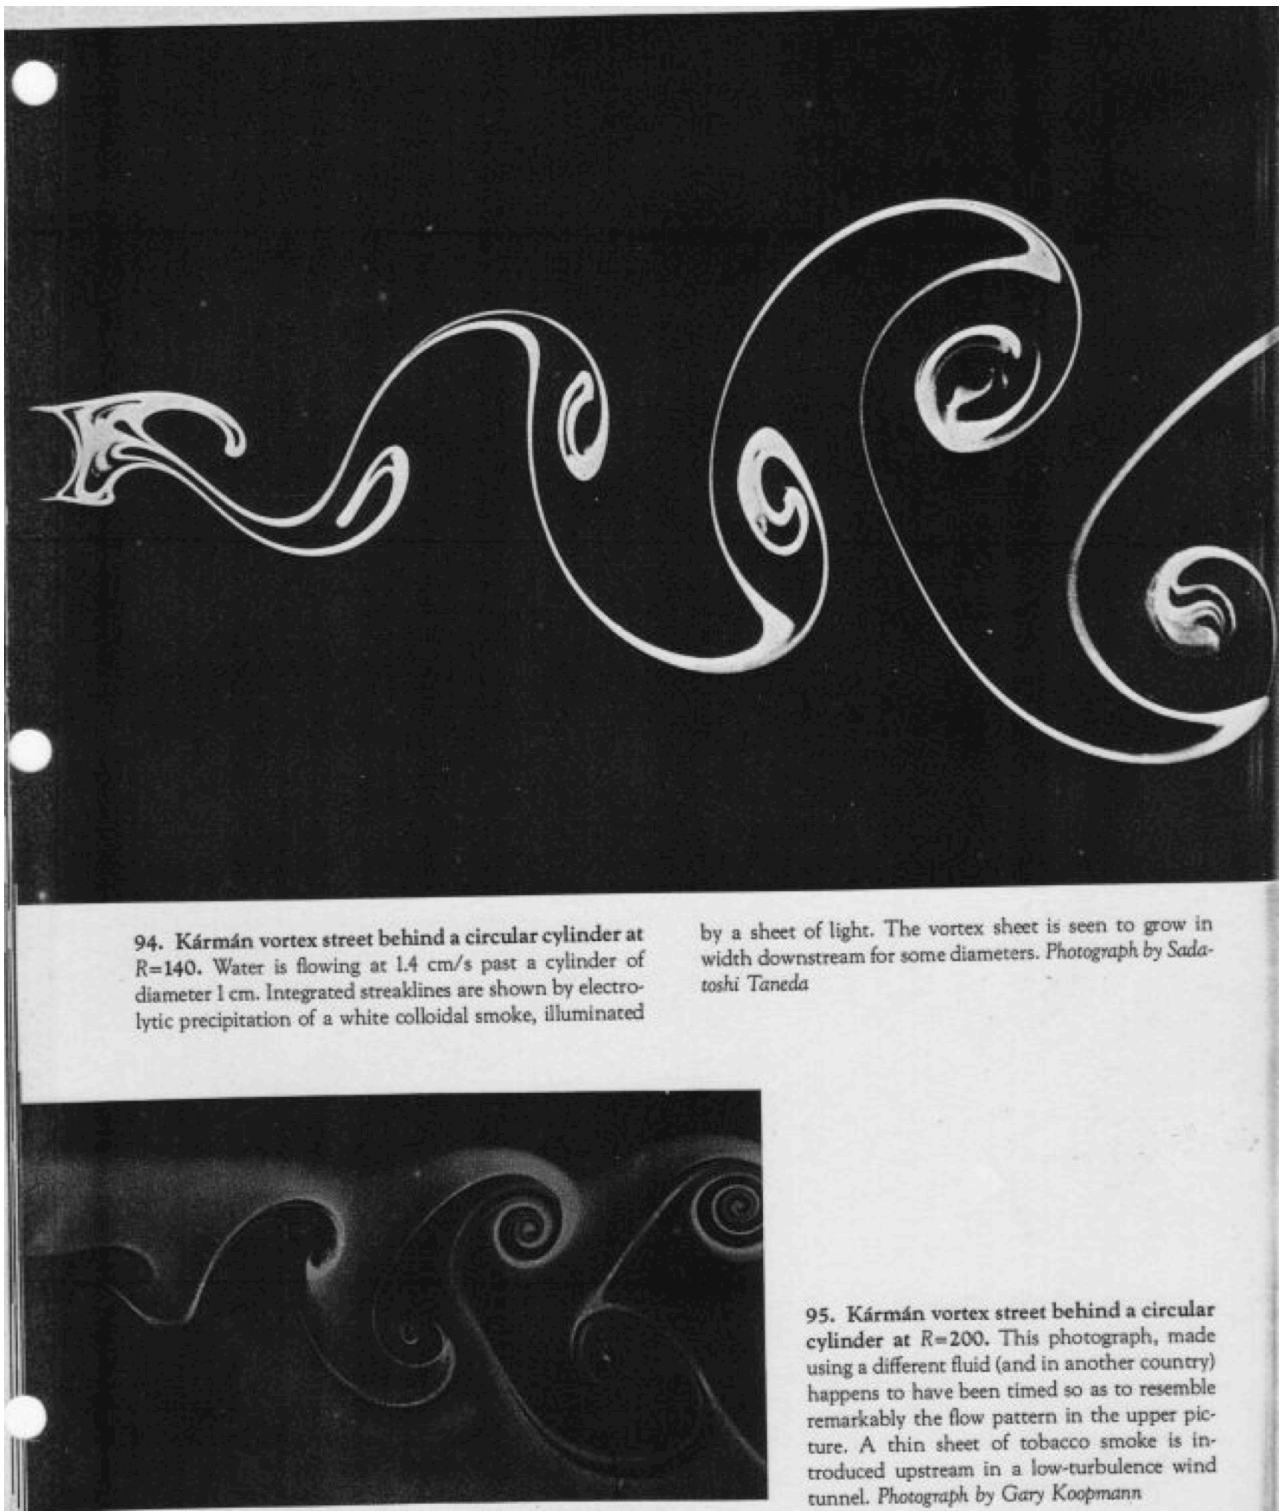

Figure 4.12.1. Streamlines of steady flow (from left to right) past a circular cylinder of radius a ; $R = 2aU/\nu$. The photograph at $R = 0.25$ (from Prandtl and Tietjens 1934) shows the movement of solid particles at a free surface, and all the others (from Taneda 1956*a*) show particles illuminated over an interior plane normal to the cylinder axis.

(From Batchelor, G.K., *An Introduction to Fluid Dynamics*, Cambridge University Press.)

94. Kármán vortex street behind a circular cylinder at $R=140$. Water is flowing at 1.4 cm/s past a cylinder of diameter 1 cm. Integrated streaklines are shown by electrolytic precipitation of a white colloidal smoke, illuminated

by a sheet of light. The vortex sheet is seen to grow in width downstream for some diameters. Photograph by Sada-toshi Taneda

95. Kármán vortex street behind a circular cylinder at $R=200$. This photograph, made using a different fluid (and in another country) happens to have been timed so as to resemble remarkably the flow pattern in the upper picture. A thin sheet of tobacco smoke is introduced upstream in a low-turbulence wind tunnel. Photograph by Gary Koopmann

(From Van Dyke, M., *An Album of Fluid Motion*, Parabolic Press.)

96. Kármán vortex street behind a circular cylinder at $R=105$. The initially spreading wake shown opposite develops into the two parallel rows of staggered vortices that von Kármán's inviscid theory shows to be stable when the ratio of width to streamwise spacing is 0.28. Streaklines are shown by electrolytic precipitation in water. Photograph by Sadatoshi Taneda

97. Smoke at various levels in a vortex street. A smoke filament in air shows, at a Reynolds number of 100, both shear layers (top photographs), only one shear layer (mid-

dle), and the irrotational flow below the wake (bottom). Zdravkovich 1969

98. Kármán vortices in absolute motion. Here the camera moves with the vortices rather than the cylinder. The streamline pattern closely resembles the inviscid one calculated by von Kármán. The flow is visualized by particles floating on water. Photograph by R. Wille, from Werlé 1973. Reproduced, with permission, from the Annual Review of Fluid Mechanics, Volume 5, © 1973 by Annual Reviews Inc.

(From Van Dyke, M., *An Album of Fluid Motion*, Parabolic Press.)

Notes:

1. The periodic shedding of vortices off the object results in periodic forces exerted on the object in the cross-stream direction. The Tacoma Narrows bridge disaster (figure shown below) occurred because a structural natural frequency of the bridge matched the frequency of the shedding vortices.

The Tacoma Narrows bridge collapsed in 1940.

2. Experimental measurements have shown that the dimensionless frequency of the shedding vortices, f , expressed as a Strouhal number, i.e., $St = fD/V$, remains relatively constant at 0.2 for $100 < Re_D < 1 \times 10^6$.

(Figure from White, F.M., *Fluid Mechanics*, McGraw-Hill.)

The fact that the Strouhal number is insensitive to the Reynolds number over a wide range of Reynolds numbers has been used to design a flow velocity meter known as the vortex flow meter (shown below).

Fig. 6.33 A vortex flowmeter. (The Foxboro Company.)

By measuring the frequency of the forces acting on the obstruction (of known size) and knowing that the Strouhal number is approximately equal to 0.2, the flow velocity can be estimated.

Fig. 8.32 Drag coefficient of a sphere as a function of Reynolds number (Ref. 13).

Commonly used curve fits to the curve shown above are:

$Re_D < 1$:	$C_D = 24/Re_D$ (Stokes' drag law)
$Re_D < 5$:	$C_D = 24/Re_D (1 + 3/16 Re_D)$ (Oseen's approximation)
$0 \leq Re_D \leq 2 \times 10^5$:	$C_D = 24/Re_D + 6/(1 + Re_D^{0.5}) + 0.4$
$Re_D < 2 \times 10^5$:	$C_D = 0.44$ (Newton's Law)

Fig. 8.34 Drag coefficient for circular cylinders as a function of Reynolds number (Ref. 13).

From the data we observe that increasing the roughness of the surface causes the drag crisis to occur at a smaller Reynolds number.

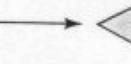

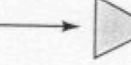

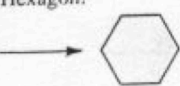

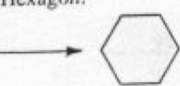

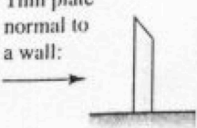

Note:

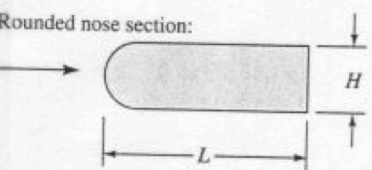

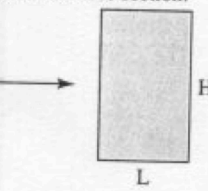

The Reynolds number for a 95 mph baseball and a 170 mph golf ball are approximately 206,000 and 213,000, respectively. Hence, both are near the drag crisis!
