(LFN) and $1/f$ noise in Cu₂O thin-film transistors (TFTs). The static direct current (DC) *I*−*V* characterization demonstrates that the channel resistance (*R*ch) contributes significantly to mobility degradation in the TFTs, with channel thickness (t_{ch}) controlled through the plasma-enhanced atomic layer deposition (PEALD) process. The 1/*f* noise followed the Hooge mobility fluctuation (HMF) model, and it was observed that both Coulomb and phonon scattering within the channel, which increased with a decrease in t_{ch} , contributed simultaneously. Increased R_{ch} contributed more significantly to the $1/f$ noise than to the contact resistance (R_C) , as evidenced by the R_C configuration of the measurements, which also revealed that R_C depends upon t_{ch} . This study demonstrates that t_{ch} is a major noise source in $Cu₂O$ TFTs and presents guidelines for the development of $Cu₂O$ TFTs and potential high-mobility p-type oxide semiconductors.

KEYWORDS: *copper(I) oxide semiconductor, low-frequency noise, Hooge mobility fluctuation, transmission line method (TLM), channel resistance, scattering, Arrhenius plot*

■ **INTRODUCTION**

The valence band (VB) of oxide semiconductors (OS) is defined by a flat and localized O 2p-derived feature at the top and a deep valence band maximum. It results in holes being effectively trapped by defects such as oxygen vacancies with relatively low energy, thereby leading to a severe bottleneck in hole mobility ($μ_h$).^{1−[4](#page-7-0)} Unlike the VB, the conduction band (CB) of the OS typically comprises empty *n*s orbitals ($n \geq 4$) of the heavy post-transition metal. Therefore, high electron mobility is expressed even in the amorphous phase and provides accessibility to high on/off current control.^{[5](#page-7-0)−[9](#page-7-0)} $Copper(I)$ oxide $(Cu₂O)$, a p-type oxide semiconductor, contains an intrinsic orbit from the close energy levels of the Cu 3d and O 2p orbitals. In high-quality single-crystal $Cu₂O$, the controllable hole concentration (n_h) of $10⁹ - 10¹²$ cm⁻³ contributes significantly to achieving high $\mu_{\rm b}$, exceeding >100 cm² V⁻¹ s^{-1,[5](#page-7-0)-[14](#page-8-0)} However, when Cu₂O is fabricated as a thinfilm transistor (TFT), there is a significant decrease in the carrier transport properties, which is attributed to the impact of the Schottky contact resistance (R_C) and the disordered quality of the semiconductor/oxide interface.^{[15](#page-8-0)−[19](#page-8-0)}

The power spectral density (PSD) represents the correlation between signal power and frequency. That can be improved based on the low-frequency noise (LFN) measurement time, which is inefficient for achieving high system accuracy because it increases the measurement time in digital electronic devices. It is essential to understand the random fluctuations occurring at low frequencies for application in electronic devices and integrated circuits.^{[20](#page-8-0)−[23](#page-8-0)} Therefore, LFN is appropriate for analyzing the charge transport mechanisms because it is always present in electronic materials and devices at the nanoscale as a determining component for the signal lower limit of both analog and digital integrated circuits. Typically, the flicker noise $(1/f)$ is considered in the frequency range of less than several kilohertz (kHz). The 1/*f* noise is represented by the Hooge mobility fluctuation (HMF) of the Hooge model when current fluctuations occur owing to phonon scattering or impurity scattering and the charge number fluctuation (CNF) of the McWhorter model when the current fluctuates due to the trapping/detrapping effect of the carrier between the gate oxide and channels.^{24–[28](#page-8-0)} However, because the CNF model was originally based on single-crystal Si-based field-effect transistors, attempts have been made to interpret the OS with opposite conduction mechanisms as models reflecting the \overrightarrow{HMF} and R_C .^{[22,23](#page-8-0)}

Figure 1. (A) Three-dimensional structure of $Cu₂O$ TFT and the resistance model manufactured in this study. (B and C) TEM images of approximately 30 nm (1200 cycles) and 100 nm (3600 cycles) $Cu₂O$ thin films deposited through the PEALD process and OM images of 30 and 100 nm Cu2O TFTs with inserted TLM patterns. (D) High-resolution photoelectron spectrum on the Cu 2p binding energy region of the PEALD Cu₂O thin-film surface. (E) XPS depth profile of the Cu 2p binding energy region of the PEALD Cu₂O thin film. (F) Wide scan energy spectrum of 30 and 100 nm $Cu₂O$ thin films.

In this article, we investigate the low-frequency noise in $Cu₂O$ TFTs for the first time and discuss the mechanism of their mobility degradation. Our results are interpreted in terms of the HMF model, which is generally used for mobility analysis in p-type semiconductors.^{[29](#page-8-0)} The scattering-related noise is observed to increase throughout the channel due to impurity-dependent Coulomb scattering and phonon scattering by the lattice vibration as the thickness (t_{ch}) scales down. The channel and contact noise were found to depend upon the length (L_{ch}) , width (W_{ch}) , and t_{ch} , which are components of the OS channels. The reduction in the mobility of $Cu₂O$ TFTs with controlled t_{ch} through the plasma-enhanced atomic layer deposition (PEALD) process was investigated via various electrical analyses, along with LFN. The parameters affecting the mobility, such as R_C , channel resistance (R_{ch}) , temperature function, and surface roughness of the $Cu₂O$ TFTs, were comprehensively investigated. Furthermore, this study revealed that the degradation in mobility decreased significantly with a decrease in t_{ch} . This suggests that the mobility degradation of the Cu₂O TFTs can be attributed to the Schottky contacts and interfaces, as reported in previous studies, and to the entire $Cu₂O$ TFT structure.

■ **RESULTS AND DISCUSSION**

Figure 1A depicts the three-dimensional (3D) structure of the Cu₂O TFT fabricated in this study and the defined R_C and R_{ch} . The $Cu₂O$ thin film was deposited in 1200, 1600, and 3600 cycles through the PEALD process to adjust the thickness. The detailed device fabrication process is presented in the [Experimental](#page-6-0) Methods.^{[30](#page-8-0),[31](#page-8-0)} Panels B and \tilde{C} of Figure 1 show the transmission electron microscopy (TEM) cross-sectional images of the $Cu₂O$ TFT. The $Cu₂O$ deposited with 1200 cycles and 3600 cycles was found to have a thickness of

approximately 30 and 100 nm, respectively, and the color of the thin film changed from blue to yellow as the thickness increased through the insertion image. [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S1 of the Supporting Information presents the TEM images captured at 100 nm intervals, including the 40 nm $Cu₂O$ thin film deposited at 1600 cycles. The transmission line method (TLM) pattern with *L*ch of 5, 10, 20, 40, and 80 *μ*m was formed as an electrode with a size of $100 \times 100 \ \mu \text{m}^2$, which can be confirmed in the inserted optical microscopy (OM) images presented in panels B and C of Figure 1. The chemical composition of the $Cu₂O$ thin film was characterized using energy-dispersive X-ray spectroscopy (EDS) in scanning transmission electron microscopy (STEM) mode, as shown in [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S2 of the Supporting Information. Cu was strongly detected in a relatively thick 100 nm $Cu₂O$ thin film, indicating an uneven distribution in which Cu appeared to be shortcircuited in some of the measurement areas. The time-of-flight secondary ion mass spectrometry (ToF-SIMS) analysis in [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S3 of the Supporting Information shows a thickness contrast exceeding 3-fold, resembling the thickness variation observed in the TEM image comparison. The roughness of the $Cu₂O$ TFT was significantly increased during postdeposition annealing (PDA) employing through the PEALD process to achieve a uniform ultrathin film, as shown in the TEM image and the atomic force microscopy (AFM) image in [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S4 of the Supporting Information.^{[32](#page-8-0)–[34](#page-8-0)} Based on previous research results on $Cu₂O$ TFTs, it was noted that the particle size increased by approximately 8 times during PDA in a vacuum atmosphere, and the particle structure merged with the increase in temperature during PDA, but this induced the formation of the $Cu₂O$ phase.^{[11](#page-7-0),[32,33](#page-8-0)} The high surface roughness of the $Cu₂O$ thin film contributed to the formation of a non-uniform electrode, but it was deposited cleanly

without gap at the metal−semiconductor junction and the related TEM image can be confirmed in [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S5 of the Supporting Information. Panels D−F of [Figure](#page-1-0) 1 depict the surface, depth profiling, and wide scan energy spectrum of $Cu₂O$ TFTs analyzed through X-ray photoelectron spectroscopy (XPS), respectively, where the peak fitting of the $Cu⁺$ peak indicates the formation of $Cu₂O$ thin films.^{[10](#page-7-0)[,35,36](#page-8-0)} However, the presence of some parasitic Cu^{2+} peaks in [Figure](#page-1-0) [1](#page-1-0)D indicates that in some $Cu₂O$ lattices, oxygen is combined with copper, leading to a thermodynamic transformation to CuO. The band gaps of Cu₂O and CuO are 2.0−2.2 and 1.2− 1.7 eV, respectively, so oxidation from $Cu₂O$ to CuO can lead to increased leakage current, potentially lowering the current on–off ratio. Additionally, the mobility degradation of Cu₂O TFTs is inherently affected by the higher effective mass associated with CuO formation.¹⁰ [Figure](#page-1-0) 1E shows that this transformation is a non-consideration since it moves away from the surface. Furthermore, we employed Ni electrodes to effectively reduce the Schottky barrier of the $Cu₂O$ films based on the findings of previous studies.¹⁶ [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S6 of the Supporting Information presents the ultraviolet photoelectron

spectroscopy (UPS) spectrum. It is assumed that the mobility degradation of the Cu₂O TFT in R_{ch} is severely reduced through the low Schottky barrier of $Cu₂O$ and Ni junctions.

Figure 2A shows the transfer characteristics of the $Cu₂O$ TFTs with a 5 *μ*m channel and thickness of 30, 40, and 100 nm, demonstrating that the on−off current is effectively controlled in the 30 nm thick TFT when compared to the 100 nm thick $TFT.³⁷$ $TFT.³⁷$ $TFT.³⁷$ [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S7 of the Supporting Information depicts the transfer, and output characteristics of the 30, 40, and 100 nm $Cu₂O$ TFTs in different voltage ranges. Figure 2B presents a comparison of the field-effect mobility (μ_{FE}) characteristics estimated from the transconductance (g_m) . Consequently, the 30 nm $Cu₂O$ TFT lower mobility than the 100 nm $Cu₂O$ TFT, which can be expected to degrade the mobility with the t_{ch} of the Cu₂O TFT. Figure 2C presents the effective mobility (μ_{eff}) corresponding to the t_{ch} , which indicates that the resistance effect caused by the thickness variations must be carefully examined as a main contributing component to the mobility degradation in $Cu₂O TFT.³$ Conversely, the hall mobility of the epitaxially grown $Cu₂O$ thin films known as high mobility p-type semiconductors, was

Figure 3. (A and D) S_{I_D}/I_D^{-2} compared to the frequency of 30 nm Cu₂O TFT; S_{I_D}/I_D^{-2} increase occurs from –40 V. (B and E) S_{I_D}/I_D^{-2} compared to the frequency of 40 nm Cu₂O TFT; S_{I_D}/I_D^2 increase occurs from −25 V. (C and F) S_{I_D}/I_D^2 compared to the frequency of 100 nm Cu₂O TFT; S_{I_D}/I_D^2 $I_{\rm D}^2$ increase occurs from −15 V. (G) $S_{I_{\rm D}}/I_{\rm D}^2$ compared to the drain current of the 30, 40, and 100 nm Cu₂O TFT; $S_{I_{\rm D}}/I_{\rm D}^2$ follows the HMF model in the linear region and increases due to the resistance effect when it reaches the saturation region. (H) α_H corresponds to V_G . (I) Comparison of Coulomb scattering effects through the extraction of $\alpha_{\rm sc}$.

estimated to decrease rapidly due to the Fermi level pinning or trap states in the channel and/or interface.^{[11](#page-7-0)} [Figure](#page-2-0) 2D presents the capacitance density of $Cu₂O$ TFT compared to the V_G value measured at frequencies of 100 and 1000 Hz, and the amount of charge that is proportionally accumulated decreases as t_{ch} decreases.

To characterize the resistance effect corresponding to $Cu₂O$ thin-film thickness, we implemented the channel resistance method (CRM) based on the gate bias and the TLM excluding the gate bias influence.[39](#page-8-0)[−][45](#page-8-0) [Figure](#page-2-0) 2E compares the resistance obtained through the CRM method, and the R_C of 30 nm $Cu₂O TFT$ increased by approximately 4 times the R_C value when compared to that of the 100 nm $Cu₂O TFT.³⁹⁻⁴¹$ $Cu₂O TFT.³⁹⁻⁴¹$ $Cu₂O TFT.³⁹⁻⁴¹$ $Cu₂O TFT.³⁹⁻⁴¹$ $Cu₂O TFT.³⁹⁻⁴¹$ [Figure](#page-2-0) [2](#page-2-0)F presents the *I*−*V* measurement of the Cu₂O TFT with t_{ch} of 30, 40, and 100 nm, confirming the formation of a low Schottky barrier in the $Cu₂O TFT$ due to the Ni electrodes, as mentioned above.[16](#page-8-0) Panels G−I of [Figure](#page-2-0) 2 depict the respective total resistances (R_T) separated through the TLM pattern, which can be obtained as $R_T = 2R_{\text{metal}} + 2R_C +$ R_{ch} ^{[42](#page-8-0)−[44](#page-8-0)} R_{C} and R_{ch} can be extracted through linear fitting by analyzing the slope of the linear region, with R_{metal} being negligible. The resistance estimated through the CRM and TLM methods was observed to increase rapidly with the decrease in t_{ch} in the Cu₂O TFT (based on the 30 nm Cu₂O TFT when compared to the 100 nm $Cu₂O$ TFT by TLM the method: R_C = approximately 130 times, R_{ch} = approximately 340 times).

The identified R_C and R_{ch} values indicate a clear potential for shorter channel lengths and lower thicknesses to be significant factors in further reducing *μ*eff. Panels A−F of Figure 3 show the representative normalized drain current spectral density (S_{I_D}/I_D^2) versus frequency characteristics of the Cu₂O TFTs for channel thicknesses of 30, 40, and 100 nm, respectively. The I_D dependence of S_{I_D} in panels A–F of Figure 3 can be found in [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S8 of the Supporting Information. The results were measured by sequentially increasing the gate bias of the Cu₂O TFT in a linear region (V_D = −10 V) and were normalized to the sensitivity and drain current values through the direct current (DC) *I*−*V* measurement. S_{I_D}/I_D^2 decreased

Figure 4. (A−C) S_{ID}/I_D² compared to the frequency of 30, 40, and 100 nm Cu₂O TFTs measured under the same conditions for each *L_{ch} through* TLM pattern. (D) L_{ch} versus S_{I_D}/I_D^2 . (E) Noise origin of the Cu₂O TFT closely correlates to the channel compared to $S_{I,ch}/I_D^2$ shown in panel D, when compared to the *L*_{ch} defined by [eq](#page-5-0) 4.

as |*V*_G| increased (panels A–C of [Figure](#page-3-0) 3) but increased inversely when a specific $|V_G|$ was applied. The turn-up in S_{I_D}/I $I_{\rm D}^2$ occurs when significant contact noise $(S_{R_{\rm C}})$ prevails over the channel resistance noise $(S_{R_{ch}})$ at a high drain current.^{[27](#page-8-0)[,46](#page-9-0)} In panels D−F of [Figure](#page-3-0) 3, the resistance-related noise increases only with a small gate bias in the 100 nm $Cu₂O TFT$ when compared to the 30 nm $Cu₂O$ TFT. This result indicates that the intrinsic R_{ch} of the 30 nm Cu₂O TFT is directly involved in the reduced mobility compared to R_{ch} of a 100 nm $Cu₂O$ TFT. [Figure](#page-3-0) 3G shows the concurrence between the HMF model, expressed as $1/I_{\rm D}$ and the noise properties of the $Cu₂O$ TFT accounting for the noise properties in the subthreshold region. This indicates that the physical noise of the $Cu₂O$ TFT corresponds to phonon lattice scattering of holes within the bulk. The HMF model causes random mobility fluctuations, as follows:

$$
\frac{S_{I_{D}}}{I_{D}^{2}} = \frac{\alpha_{\text{H}}q}{fC_{\text{ox}}WL(V_{\text{G}} - V_{\text{T}})}\tag{1}
$$

where f is the frequency, C_{ox} is denotes the gate oxide capacitance per unit area, *q* is the electron charge, and *W* and *L* are the channel length and width, respectively. The Hooge parameter (α_H) is commonly used as a performance index for comparing various device technologies and its numerical value is proportional to that when phonon lattice scattering occurs strongly.^{[25](#page-8-0),[28](#page-8-0)} [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S9 of the Supporting Information, presents a comparison with the CNF model, which is the carrier trapping/detrapping effect from the $Cu₂O$ TFT to the gate oxide. S_{I_D}/I_D^2 demonstrated a significant difference from the trend of $(g_m/I_D)^2$, which indicates that the charge transport mechanism of the $Cu₂O$ TFT follows the HMF model.

[Figure](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S10A of the Supporting Information depicts the relationship between γ and V_G , which is the slope of the algebraic relationship between S_{I_D} and *f* of the Cu₂O TFT [γ = *−∂*ln(*S_{I_D*)/*∂*ln(*f*)]. The slope becomes smaller if parasitic noise} other than the $1/f$ noise is affected. Thus, a decrease in the t_{ch} value induces a parasitic resistance effect; thus, a reduction in the thickness of the $Cu₂O$ TFT is considered an additional noise source. In [Figure](#page-3-0) 3H, the α_H extracted from the HMF model is significantly higher than the commonly known value (10[−]⁴ −10[−]⁶)[.47](#page-9-0) Based on the fatally high roughness and its nature as a p-type semiconductor, α_H of Cu₂O TFT is considered a sufficiently probable value. [Table](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S1 of the Supporting Information presents the α_H values of p/n-type semiconductors, and the α_H value of the Cu₂O TFT reported in this paper is similar to that of the reported p-type semiconductor. α _H decreases when the gate bias increases in the weak inversion region. The degradation persisted up to the peak voltage of *g*^m because the transfer properties influenced the lattice-related scattering effect more proactively. The R_C effect becomes more prominent with a further increase in the gate bias, leading to an increase in the α_H. [Figure](#page-3-0) 3I gives the Coulomb scattering parameter $(\alpha_{\rm sc})$ extracted from the S_{I_D}/I_D^2 of the equivalent gate voltage noise (S_{VG}) .^{[48,49](#page-9-0)} α_{sc} is valid only for FETs with bulk channels. *α*_{sc} recorded values nearly 30 times higher in 30 nm $Cu₂O$ TFTs than in 100 nm $Cu₂O$ TFTs, indicating that the scattering effects by the impurities are latent despite the low thickness. Strong Coulomb scattering effects on the LFN properties can be partly attributed to unwanted external noise sources presented by R_C or the electrical barrier height.[50](#page-9-0)−[52](#page-9-0) The *μ*eff determined in [Figure](#page-2-0) 2B is derived from the mobility by Coulomb scattering and phonon scattering, based on Matthiessen's rule. Therefore, due to the thickness reduction of the Cu₂O TFT, μ_{eff} is reasonably

Figure 5. (A−C) Richardson plot compared to the temperature of a 30, 40, and 100 nm Cu₂O TFT with a 5 µm channel. (D-F) Temperature versus Φ_B defined through the Arrhenius plot. The legend includes the R^2 value for linear fit accuracy, along with the linear equation for $V_D = -4$ V.

assumed to be limited to the two scattering effects analyzed from the LFN characteristics of panels G and H of [Figure](#page-3-0) 3. The following assumptions can be emphasized for $Cu₂O$ TFTs with Ti electrodes that maximize Schottky barrier effects and are discussed in detail in [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S11 of the Supporting Information. The error bars in panels B and C of [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S10 of the Supporting Information depict a comparison of the scattering parameters of several devices.

It was observed in [Figures](#page-2-0) 2 and [3](#page-3-0) that R_{ch} is more involved than R_C as a major μ_{eff} degradation mechanism for the Cu₂O TFTs.⁵³ By utilizing the characteristic that R_C was proportional to W_{ch} and not dependent upon L_{ch} , we focused only on the effects of R_{ch} by maintaining W_{ch} at a constant value and varying L_{ch} to analyze the mobility degradation mechanism.²² Panels A−C of [Figure](#page-4-0) 4 show the S_{I_D}/I_D^2 results of the 30, 40, and 100 nm Cu₂O TFTs whose L_{ch} was increased 2 times from 5 μ m through the TLM pattern. The S_{I_D}/I_D^2 comparison was performed under the condition of a gate/drain bias $(-10/-10)$ V), which is the linear region of all devices, indicating that both the elements constituting the channel $(L_{\text{ch}}$, $W_{\text{ch}})$ and the applied voltage are identical except for the channel thickness. Notably, panels A–C of [Figure](#page-4-0) 4 depict opposite S_{I_D}/I_D^2 movements, suggesting that t_{ch} of the Cu₂O TFT influenced $1/f$. To verify this trend, S_{I_D}/I_D^2 was assumed to be the total resistance noise (S_{R_T}) caused by uncorrelated R_ch and R_C based on the following equation:

$$
\frac{S_{I_{\rm D}}}{I_{\rm D}^2} = \frac{S_{R_{\rm T}}}{R_{\rm T}^2} = \frac{S_{R_{\rm ch}} + S_{R_{\rm C}}}{(R_{\rm ch} + R_{\rm C})^2}
$$
(2)

In a previous study analyzing the LFN of nanocrystal fieldeffect transistors, four components $(S_{R_{\rm{ch}}},S_{R_{\rm{C}}},R_{\rm{ch}},\, {\rm{and}}\; R_{\rm{C}})$ were reported on the *W*ch- and *L*ch-dependent noise of the channel. 22 However, in the case of metal oxide semiconductors such as $Cu₂O$ TFTs, the t_{ch} effect must be reflected because the bulk channel participates in current conduction. [Figure](https://pubs.acs.org/doi/suppl/10.1021/acsami.4c14876/suppl_file/am4c14876_si_001.pdf) S12 of the Supporting Information presents the ratio of R_C and R_{ch} to R_T extracted from DC *I*−*V* in the linear region by applying a gate bias of −10 V. In comparison, the *R*_C ratio at this voltage decreased as L_{ch} increased. Both R_{ch} and $S_{R_{ch}}$ significantly affect the $1/f$ shape when compared to R_C and S_{R_C} and are expressed as follows:

$$
\frac{S_{I_{\rm D}}}{I_{\rm D}^2} = \frac{S_{R_{\rm T}}}{R_{\rm T}^2} = \frac{S_{R_{\rm ch}}}{R_{\rm ch}^2} \propto \frac{\frac{a_{\rm ch}R_{\rm ch}^2}{N_{\rm ch}^2}}{R_{\rm ch}^2} \propto \frac{1}{N_{\rm ch}} = \frac{1}{L_{\rm ch} \times W_{\rm ch} \times t_{\rm ch}}
$$
(3)

where N_{ch} denotes the free carriers in the channel region. It corresponds to L_{cb} , W_{cb} , and t_{cb} , and can be simplified as $N_{\text{ch}} \propto$ $L_c \times W_{ch} \times t_{ch}$. Meanwhile, R_{ch} has a proportional relationship with $L_{ch}/(W_{ch} \times t_{ch})$. In the fabricated 100 nm Cu₂O TFT, W_{ch} and t_{ch} are constant, and the S_{I_D} variable follows the $L_{ch}^$ dependence, indicating that the linear fitted gradient of L_{ch} versus S_{I_D} (10 Hz) is consistent with $m = -1$ in [Figure](#page-4-0) 4D. The gradient of the 100 nm $Cu₂O$ TFT corresponds to the dependence of R_{ch} and $S_{R_{ch}}$, as reported in previous studies. In the 30 nm $Cu₂O$ TFT that presents a difference of approximately 0.3 times in t_{ch} , the change in the gradient of L_{ch} versus S_{I_D} corresponding to the t_{ch} change is observed in [Figure](#page-4-0) 4D. According to our modified relational expression, the S_{R_T} variable of the 30 nm $Cu₂O$ TFT follows a dependence of 3 \times L_{ch}^{-1} , which demonstrates that the logarithmic calculated gradient is 0.5, which is consistent with the actual measurement value. The channel noise data were analyzed using the following formula to understand the physical origin of the slope: 24

S I

[Figure](#page-4-0) 4E shows the slope of the channel-current PSD $(S_{Lch}$ I_{D}^{2}) normalized to L_{ch} versus the drain current; the values extracted from the TLM method were used for *R_C*. The linear fitted slope in [Figure](#page-4-0) 4E is similar to the slope of $S_{I_{\mathrm{D}}}/I_{\mathrm{D}}^{-2}$ in the $Cu₂O TFT$, as shown in [Figure](#page-4-0) 4D, indicating that the origin of the Cu₂O TFT noise depends upon t_{ch} as well as L_{ch} and W_{ch} of the Cu₂O thin films.

From the LFN results of the Cu₂O TFT, both the *R*_{ch} of the $Cu₂O TFT$ and the R_C effect that occurred between the thin film and the Ni electrode were verified from the thermionic emission model through the Richardson plot, which is a type of Arrhenius plot, across a temperature range of 300 to 360 K. Panels A–C of [Figure](#page-5-0) 5 present the Richardson plots of Cu₂O TFTs with t_{ch} of 30, 40, and 100 nm respectively, which are used to estimate the effective Richardson constant (*A**) and zero bias Schottky barrier height (Φ_B) .^{[44](#page-8-0),[54](#page-9-0)–[56](#page-9-0)} *A** of a 30, 40, and 100 nm $Cu₂O TFT$ was estimated to be 0.00098, 0.00328, and 0.03246 A cm^{-2} K⁻² from plot intercepts, respectively. The significantly lower values obtained when compared to the theoretical predictions indicate the impact of a smaller active area relative to the device area and the effects of barrier inhomogeneities. The quantified Φ_B is expressed as follows:

$$
\Phi_{\rm B} = \frac{kT}{q} \ln \left(\frac{A_{\rm d}A^* T^2}{I_{\rm D}} \right) \tag{5}
$$

where *k* is Boltzmann's constant, *T* is the absolute temperature, A_d is the channel region, and I_D is the drain current. The temperature versus Φ_B was investigated using Arrhenius plot for 1000/*T* in panels D−F of [Figure](#page-5-0) 5. [55](#page-9-0)−[57](#page-9-0) The proportionality between t_{ch} and Φ_B was observed, but for the $Cu₂O$ TFTs with the same t_{cb} , the influence of temperature on Φ_B is minimal. Similarly, our results indicate that the instabilities related to 1/*f* noise and thermal function increase within the device because R_{ch} is inversely proportional to the $Cu₂O$ film thickness.

Figure 6 depicts the mobility degradation factors arising from the t_{ch} scaling of Cu₂O TFT. The Cu₂O TFTs with bulk

Figure 6. Schematic of the summarized noise-causing element by t_{ch} scaling of $Cu₂O$ TFT.

conduction mechanisms were evaluated to increase the phonon/Coulomb scattering, Φ_B , and temperature instability in the bulk as the t_{ch} is scaled. In particular, the $1/f$ noise level incorporating these factors was verified to be associated with *t*ch. Thus, maintaining a uniform film quality is crucial for preserving the mobility of $Cu₂O$ TFTs, which are promising candidates for p-type semiconductors.

■ **CONCLUSION**
In summary, we reported the 1/*f* noise behavior at low frequencies in $Cu₂O$ TFTs and correlated the noise behavior with the reduced mobility owing to scattering inside the $Cu₂O$ thin film. The $1/f$ noise behavior of the $Cu₂O$ TFTs, whose thicknesses were adjusted through the PEALD process, is consistent with the HMF model commonly used for p-type semiconductors. The *R*_{ch} defined by the DC *I*−*V* characteristics varied noticeably with the thickness change of the $Cu₂O$ thin film when compared to *R_C*. The PSD behavior concerning L_{ch} and the difference t_{ch} of the Cu₂O TFTs was found to be opposite, and was dependent upon the PSD through the correlation of the channel components. Furthermore, temperature measurements reinforced the claim of mobility degradation with thickness dependence and the scattering mechanism in the thin film. Our results contribute significantly to the development of oxide semiconductor-based electronic devices and provide a better understanding of the mobility degradation mechanisms of p-type semiconductors and the random fluctuations occurring at low frequencies. In particular, the evaluation platform for PSD, which is inversely proportional to the proposed t_{ch} can be versatile when evaluating the noise in semiconductors with bulk conduction mechanisms.

■ **EXPERIMENTAL METHODS**
 Device Fabrication. The Cu₂O TFT was fabricated in a bottom gate structure in which $SiO₂$ was grown to 90 nm through thermal growth and served as a gate dielectric layer. A p⁺-doped silicon substrate served as the gate. The $Cu₂O$ channel material was deposited on $SiO₂$ through the PEALD process.²⁵ Subsequently, the rapid thermal annealing (RTA) process was performed at 700 $^{\circ}$ C for 5 min in a N_2 atmosphere. The TLM pattern of the Cu_2O TFT was formed by UV exposure and 100 nm of Ni was deposited using an electron-beam evaporator. The $Cu₂O$ thin films used in this study were deposited under similar conditions.

Device Characterization and Low-Frequency Noise Measurement. Five samples each with different thicknesses (30, 40, and 100 nm) were measured, and the average and standard error values for these values are represented as error bars. To prepare for unexpected effects when measuring the $Cu₂O$ TFTs, measurements were performed using a Keithley 4200A-SCS parameter analyzer in a vacuum chamber at room temperature. The *C*−*V* curve was measured using a Kesight E4980A Precision LCR meter. To collect the 1/*f* noise, we minimized external interference by connecting a suitable shared ground and shielding with a SR570 low-noise current preamplifier and an 89410A vector signal analyzer. The SR570 amplifies the input current to the output voltage and transmits the signal at 89410A. The 89410A was measured in units of 4 Hz from 10 to 1610 Hz, with 10 results derived from the average for a stable output. White noise was frequently observed above 1000 Hz and was omitted from the visualization.
